ACKNOWLEDGMENTS

First and foremost I thank God for giving me the strength, stamina, ability and knowledge to complete this long and arduous path. Without the belief that my work was to be of some durable value I never could have completed it.

I owe much to my committee. Ed Riseman, whose pen I have come to dread, gave me invaluable advice and criticism not only in this dissertation but for my professional life in general. Al Hanson, whose availability was much appreciated, helped in countless ways. Michael Arbib introduced me to perceptual robotics in general and mobile robotics in particular. His stimulating discussions on schemas paved the way for many of the ideas in this dissertation. Victor Lesser pushed me for answers to hard questions. Hopefully they have been answered to his satisfaction. Steve Levitan provided the perspective that was essential for me to successfully complete the work, pointing out pitfalls that other unwary students may have been trapped in.

An array of institutions and industries provided assistance in many ways. Dr. Hans Moravec of Carnegie-Mellon University provided code that was of value for use in AuRA's short-term memory. Drs. Chuck Thorpe and Martial Hebert enabled us to use the CMU NAVLAB for a motion sequence. Michael Swain of the University of Rochester supplied code for use in camera calibration. The support and assistance from Denning Mobile Robotics (special thanks to Mark Kadonoff) was superb.

A large debt of gratitude is owed to the members of VISIONS and the Laboratory for Perceptual Robotics. Special thanks to Randy Ellis, Bruce Draper, Les Kitchen, Phil Kahn, Igor Pavlin, and Mark Snyder for sharing their knowledge, expertise and code with me. Bob Heller saved me countless hours of programming thanks to his incredibly deep knowledge of the VAXen and VISIONS systems. Bennie Murah helped me to retain my sanity through this ordeal by getting me out of the lab on occasion. Our technicians, Robyn Bari, Chris Helgesen, and Jim Drewett all contributed meaningfully to this research. Thanks also to Val Cohen, Janet Turnbull, and Laurie Waskiewicz for maintaining the day-to-day operations of the VISIONS group in a manner which freed me from concern for administrative details.

The secretarial staff of the COINS department also deserves a place in these acknowledgments. Rose Korowski answered my seemingly endless questions regarding duplicating, slides, etc. Renee Stephens interfaced with the graduate school providing the

reassurance that I had not neglected any requirements for my doctorate. Thanks to you all.

Finally, I acknowledge those people to whom I owe the most, my family. My Dad whose financial assistance made this all possible and whose confidence that I could complete the work drove me on. My late mother whose memory inspired me to strive for my best. I hope I have proven to be a worthy son. My children, Matthew, Rebekah, Sarah, and Hannah, who have unquestionably made the greatest sacrifice during this time, thanks for your patience. Hopefully now I will have time to catch up on being your Dad. To Michaelle, my beloved wife, who spent countless hours taking care of the children in my absence, proofing my papers, cheering me up when I was down and keeping me on the right track, my gratitude is beyond words. This research is as much yours as mine for without you it would not have been possible.

ABSTRACT

TOWARDS COSMOPOLITAN ROBOTS:
INTELLIGENT NAVIGATION IN EXTENDED MAN-MADE ENVIRONMENTS
SEPTEMBER 1987

RONALD CRAIG ARKIN

B.S., University of Michigan

M.S., Stevens Institute of Technology

Ph.D., University of Massachusetts

Directed by: Professor Edward M. Riseman

In the past, mobile robots have been constrained to operate in either an indoor or an outdoor environment, not both. Special purpose representations and ad hoc sensor techniques geared towards tasks of narrow focus have dominated these efforts. It is the purpose of this dissertation to lead towards the development of a more cosmopolitan robot; one whose domain of interaction is not as restricted as these previous attempts.

The Autonomous Robot Architecture (AuRA) has been developed to meet these challenges. A "meadow" map, used for global path planning and containing embedded *a priori* knowledge to guide sensor expectations, serves as the robot's long term memory. A layered short term memory based on instantiated meadows represents the currently perceived world. A hierarchical path planner produces a global path free of collisions with all modeled obstacles.

Schema theory is extended to include the mobile robot domain and serves as the principal theoretical framework. The schema-based path execution system handles unexpected and dynamic obstacles not present in the robot's world model. This motor schema-based navigation system produces reactive/reflexive behavior in direct response to sensor events. In addition, new techniques in the treatment of robot uncertainty which expedite sensory processing are presented. These include the use of a spatial error map with associated error growth and reduction techniques.

Several computer vision sensor strategies have been developed for use within AuRA. These include a fast line-finding algorithm, a fast region segmentation algorithm, and a depth-from-motion algorithm. Experiments using our mobile vehicle HARV demonstrate the use of these vision algorithms for navigational purposes. Schema-based navigation using ultrasonic sensing is also demonstrated experimentally.

TABLE OF CONTENTS
