Object Detection

• Overview
• Viola-Jones
• Dalal-Triggs

• Later classes:
  – Deformable models
  – Deep learning
Person detection with HoG’s & linear SVM’s

- Histograms of Oriented Gradients for Human Detection, Navneet Dalal, Bill Triggs, International Conference on Computer Vision & Pattern Recognition - June 2005
Object detection vs Scene Recognition

• What’s the difference?
• Objects (even if deformable and articulated) probably have more consistent shapes than scenes.
• Scenes can be defined by distribution of “stuff” – materials and surfaces with arbitrary shape.
• Objects are “things” that own their boundaries
• Bag of words models less popular for object detection because they throw away shape info.
Object Category Detection

• Focus on object search: “Where is it?”
• Build templates that quickly differentiate object patch from background patch
Challenges in modeling the object class

- Illumination
- Object pose
- Clutter
- Occlusions
- Intra-class appearance
- Viewpoint

Slide from K. Grauman, B. Leibe
Challenges in modeling the non-object class

True Detections

Bad Localization

Confused with Similar Object

Confused with Dissimilar Objects

Misc. Background
General Process of Object Recognition

1. Specify Object Model
2. Generate Hypotheses
3. Score Hypotheses
4. Resolve Detections

What are the object parameters?
Specifying an object model

1. Statistical Template in Bounding Box
   - Object is some \((x,y,w,h)\) in image
   - Features defined \(wrt\) bounding box coordinates

Images from Felzenszwalb
Specifying an object model

2. Articulated parts model
   - Object is configuration of parts
   - Each part is detectable

Images from Felzenszwalb
Specifying an object model

3. Hybrid template/parts model

Detections

Template Visualization

- root filters
- part filters
- deformation models

Felzenszwalb et al. 2008
Specifying an object model

4. 3D-ish model

- Object is collection of 3D planar patches under affine transformation
General Process of Object Recognition

1. Specify Object Model
2. Generate Hypotheses
3. Score Hypotheses
4. Resolve Detections

Propose an alignment of the model to the image
Generating hypotheses

1. Sliding window
   - Test patch at each location and scale
Generating hypotheses

1. Sliding window
   – Test patch at each location and scale

Note – Template did not change size
Each window is separately classified
Generating hypotheses

2. Voting from patches/keypoints

ISM model by Leibe et al.
Generating hypotheses

3. Region-based proposal
General Process of Object Recognition

1. Specify Object Model
2. Generate Hypotheses
3. Score Hypotheses
4. Resolve Detections

Mainly-gradient based features, usually based on summary representation, many classifiers
General Process of Object Recognition

1. Specify Object Model
2. Generate Hypotheses
3. Score Hypotheses
4. Resolve Detections
   - Rescore each proposed object based on whole set
Resolving detection scores

1. Non-max suppression
Resolving detection scores

1. Non-max suppression

“Overlap” score is below some threshold
Resolving detection scores

2. Context/reasoning

(g) Car Detections: Local  (h) Ped Detections: Local

Hoiem et al. 2006
Influential Works in Detection

  - Basic idea of statistical template detection (I think), bootstrapping to get “face-like” negative examples, multiple whole-face prototypes (in 1994)
  - “Parts” at fixed position, non-maxima suppression, simple cascade, rotation, pretty good accuracy, fast
  - Careful feature engineering, excellent results, cascade
  - Haar-like features, Adaboost as feature selection, hyper-cascade, very fast
- Dalal-Triggs (2005): ~12,500 citations
  - Careful feature engineering, excellent results, HOG feature, online code
  - Template/parts-based blend
- Girshick et al. (2013): ~700 citations
  - R-CNN. Deep learned models on object proposals.

"The Nikon S60 detects up to 12 faces."
Challenges of face detection

- Sliding window detector must evaluate tens of thousands of location/scale combinations
- Faces are rare: 0–10 per image
  - For computational efficiency, we should try to spend as little time as possible on the non-face windows
  - A megapixel image has \( \sim 10^6 \) pixels and a comparable number of candidate face locations
  - To avoid having a false positive in every image image, our false positive rate has to be less than \( 10^{-6} \)
The Viola/Jones Face Detector

- A seminal approach to real-time object detection
- Training is slow, but detection is very fast
- Key ideas
  - *Integral images* for fast feature evaluation
  - *Boosting* for feature selection
  - *Attentional cascade* for fast rejection of non-face windows

Image Features

“Rectangle filters”

Value =

\[ \sum (\text{pixels in white area}) - \sum (\text{pixels in black area}) \]
Example

Source

Result

×

√
Fast computation with integral images

- The *integral image* computes a value at each pixel \((x,y)\) that is the sum of the pixel values above and to the left of \((x,y)\), inclusive.

- This can quickly be computed in one pass through the image.
Computing the integral image
Computing the integral image

Cumulative row sum: \( s(x, y) = s(x-1, y) + i(x, y) \)

Integral image: \( ii(x, y) = ii(x, y-1) + s(x, y) \)

MATLAB: \( ii = \text{cumsum(\text{cumsum(\text{double}(i)), 2})}; \)
Computing sum within a rectangle

• Let A, B, C, D be the values of the integral image at the corners of a rectangle
• Then the sum of original image values within the rectangle can be computed as:
  \[
  \text{sum} = A - B - C + D
  \]
• Only 3 additions are required for any size of rectangle!
Computing a rectangle feature
Feature selection

- For a 24x24 detection region, the number of possible rectangle features is ~160,000!
Feature selection

• For a 24x24 detection region, the number of possible rectangle features is ~160,000!
• At test time, it is impractical to evaluate the entire feature set
• Can we create a good classifier using just a small subset of all possible features?
• How to select such a subset?
Boosting

• **Boosting** is a classification scheme that combines *weak learners* into a more accurate *ensemble classifier*

• Weak learners based on rectangle filters:

\[
T_t(x) = \begin{cases} 
1 & \text{if } p_t f_t(x) > p_t \theta_t \\
0 & \text{otherwise}
\end{cases}
\]

• Ensemble classification function:

\[
C(x) = \begin{cases} 
1 & \text{if } \sum_{t=1}^{T} \alpha_t T_t(x) > \frac{1}{2} \sum_{t=1}^{T} \alpha_t \\
0 & \text{otherwise}
\end{cases}
\]
Training procedure

• Initially, weight each training example equally

• In each boosting round:
  • Find the weak learner that achieves the lowest weighted training error
  • Raise the weights of training examples misclassified by current weak learner

• Compute final classifier as linear combination of all weak learners (weight of each learner is directly proportional to its accuracy)
  • Exact formulas for re-weighting and combining weak learners depend on the particular boosting scheme (e.g., AdaBoost)

Boosting intuition

Boosting illustration

Weak Classifier 3
Final classifier is a combination of weak classifiers
Boosting for face detection

- First two features selected by boosting:

  This feature combination can yield 100% detection rate and 50% false positive rate
Boosting vs. SVM

• **Advantages of boosting**
  • Integrates classifier training with feature selection
  • Complexity of training is linear instead of quadratic in the number of training examples
  • Flexibility in the choice of weak learners, boosting scheme
  • Testing is fast

• **Disadvantages**
  • Needs many training examples
  • Training is slow
  • Often doesn’t work as well as SVM (especially for many-class problems)
Boosting for face detection

- A 200-feature classifier can yield 95% detection rate and a false positive rate of 1 in 14084

Not good enough!
Attentional cascade

- We start with simple classifiers which reject many of the negative sub-windows while detecting almost all positive sub-windows.
- Positive response from the first classifier triggers the evaluation of a second (more complex) classifier, and so on.
- A negative outcome at any point leads to the immediate rejection of the sub-window.
Attentioonal cascade

- Chain classifiers that are progressively more complex and have lower false positive rates:
Attentional cascade

• The detection rate and the false positive rate of the cascade are found by multiplying the respective rates of the individual stages

• A detection rate of 0.9 and a false positive rate on the order of $10^{-6}$ can be achieved by a 10-stage cascade if each stage has a detection rate of 0.99 ($0.99^{10} \approx 0.9$) and a false positive rate of about 0.30 ($0.3^{10} \approx 6 \times 10^{-6}$)
Training the cascade

• Set target detection and false positive rates for each stage

• Keep adding features to the current stage until its target rates have been met
  • Need to lower AdaBoost threshold to maximize detection (as opposed to minimizing total classification error)
  • Test on a validation set

• If the overall false positive rate is not low enough, then add another stage

• Use false positives from current stage as the negative training examples for the next stage
The implemented system

• Training Data
  • 5000 faces
    – All frontal, rescaled to 24x24 pixels
  • 300 million non-faces
    – 9500 non-face images
  • Faces are normalized
    – Scale, translation

• Many variations
  • Across individuals
  • Illumination
  • Pose
System performance

- Training time: “weeks” on 466 MHz Sun workstation
- 38 layers, total of 6061 features
- Average of 10 features evaluated per window on test set
- “On a 700 Mhz Pentium III processor, the face detector can process a 384 by 288 pixel image in about .067 seconds”
  - 15 Hz
  - 15 times faster than previous detector of comparable accuracy (Rowley et al., 1998)
Output of Face Detector on Test Images
Other detection tasks

Facial Feature Localization

Profile Detection

Male vs. female
Profile Detection
Profile Features
Summary: Viola/Jones detector

- Rectangle features
- Integral images for fast computation
- Boosting for feature selection
- Attentional cascade for fast rejection of negative windows
Statistical Template

Object model = sum of scores of features at fixed positions

\[ +3 +2 -2 -1 -2.5 = -0.5 > 7.5 \]

Non-object

\[ +4 +1 +0.5 +3 +0.5 = 10.5 > 7.5 \]

Object
Design challenges

How to efficiently search for likely objects

• Even simple models require searching hundreds of thousands of positions and scales

Feature design and scoring

• How should appearance be modeled? What features correspond to the object?

How to deal with different viewpoints?

• Often train different models for a few different viewpoints

Implementation details

• Window size
• Aspect ratio
• Translation/scale step size
• Non-maxima suppression
Example: Dalal-Triggs pedestrian detector

1. Extract fixed-sized (64x128 pixel) window at each position and scale
2. Compute HOG (histogram of gradient) features within each window
3. Score the window with a linear SVM classifier
4. Perform non-maxima suppression to remove overlapping detections with lower scores
