Topics:

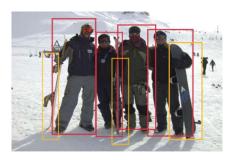

- Advanced Architectures
- Bias, Fairness, Calibration

## CS 4644-DL / 7643-A ZSOLT KIRA

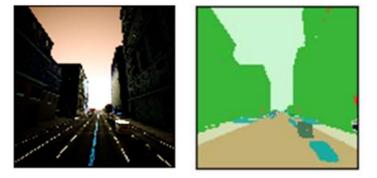

- Assignment 3 out
  - Due March 14th 11:59pm EST.
- Projects
  - Project proposal due March 13<sup>th</sup>
  - Next class: Come with project teams/ideas and run them by TAs!
- Meta Office Hours on Fairness/Bias Friday 3pm EST
  - NOT recorded!

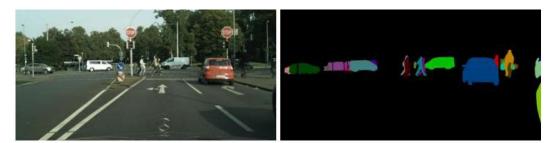

### **Classification** (Class distribution per image)

#### **Object Detection** (List of bounding boxes with class distribution per box)

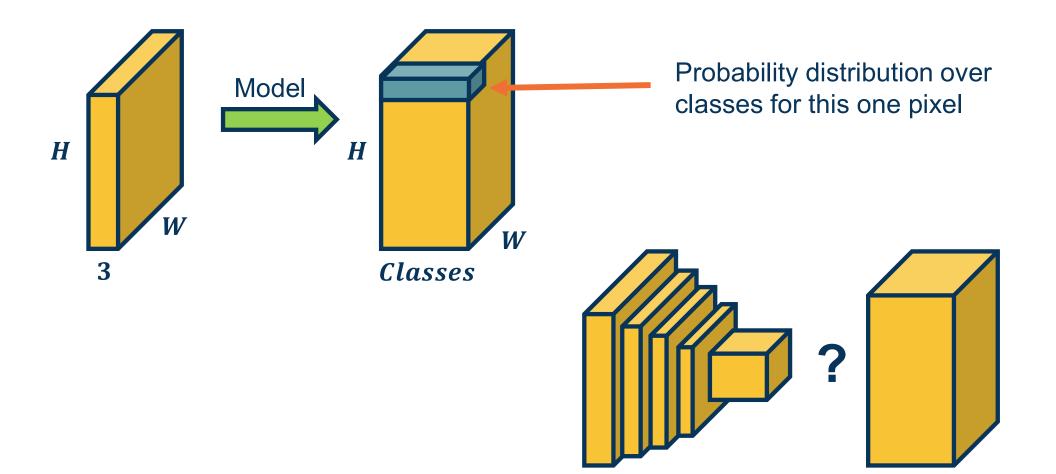

#### Semantic Segmentation (Class distribution per pixel)

#### Instance Segmentation (Class distribution per pixel with unique ID)

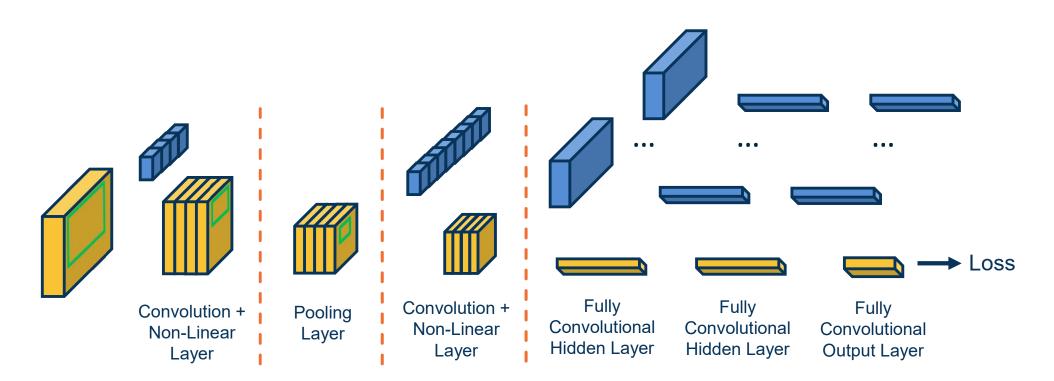

## **Computer Vision Tasks**

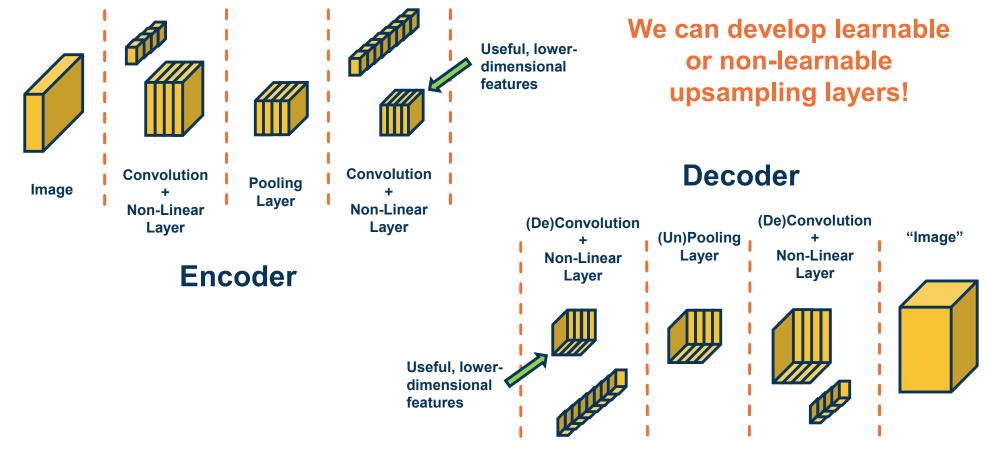

## Each kernel has the size of entire input! (output is 1 scalar)

- This is equivalent to Wx+b!
- We have one kernel per output node

**Converting FC Layers to Conv Layers** 

Idea 2: "De"Convolution and UnPooling

## Example : Max pooling

ບ ||

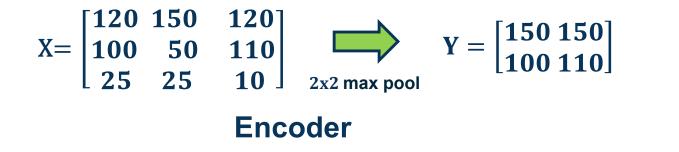

Stride window across image but perform per-patch max operation

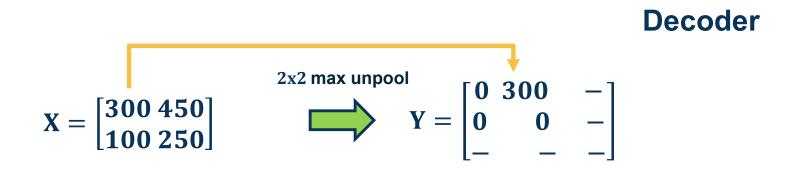

$$X(0:1,0:1) = \begin{bmatrix} 100 & 150 \\ 100 & 200 \end{bmatrix} \implies max(0:1,0:1) = 200$$
  
Copy value to position chosen as max in encoder, fill reset of this window with zeros

**Idea:** Remember max elements in encoder! Copy value from equivalent position, rest are zeros

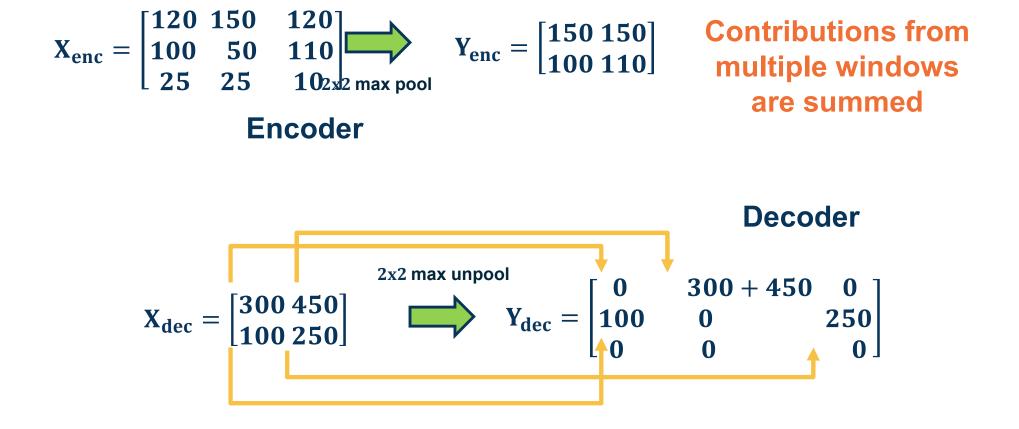

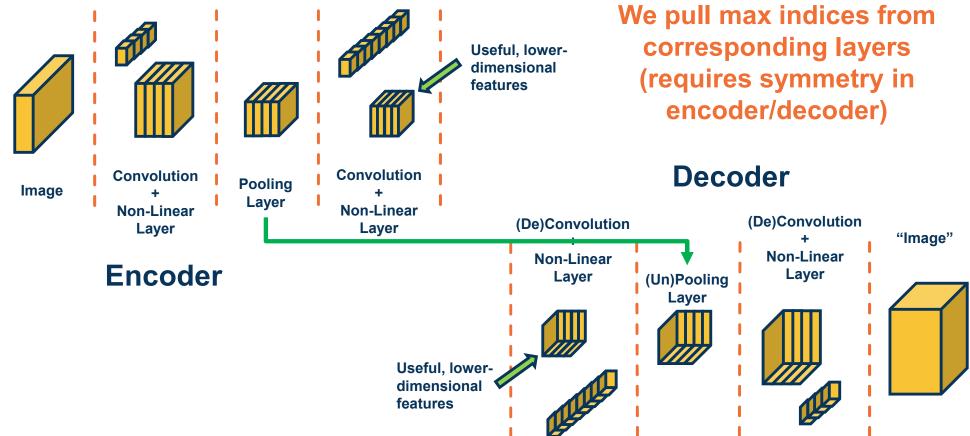

Max Unpooling Example (one window)

Max Unpooling Example

**Convolutional Neural Network (CNN)** 

Symmetry in Encoder/Decoder

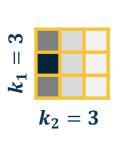

## How can we upsample using convolutions and learnable kernel?

### **Normal Convolution**

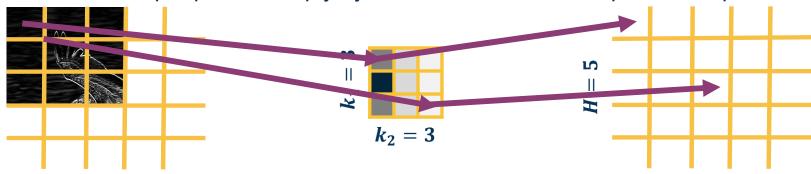

W = 5

 $W - k_2 + 1$ 

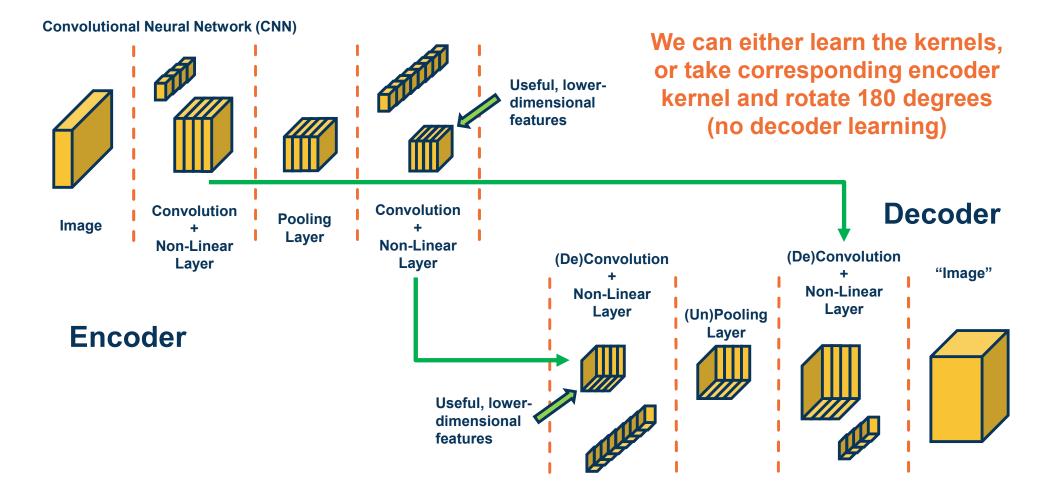

Transposed Convolution (also known as "deconvolution", fractionally strided conv) Idea: Take each input pixel, multiply by learnable kernel, "stamp" it on output

"De"Convolution (Transposed Convolution)

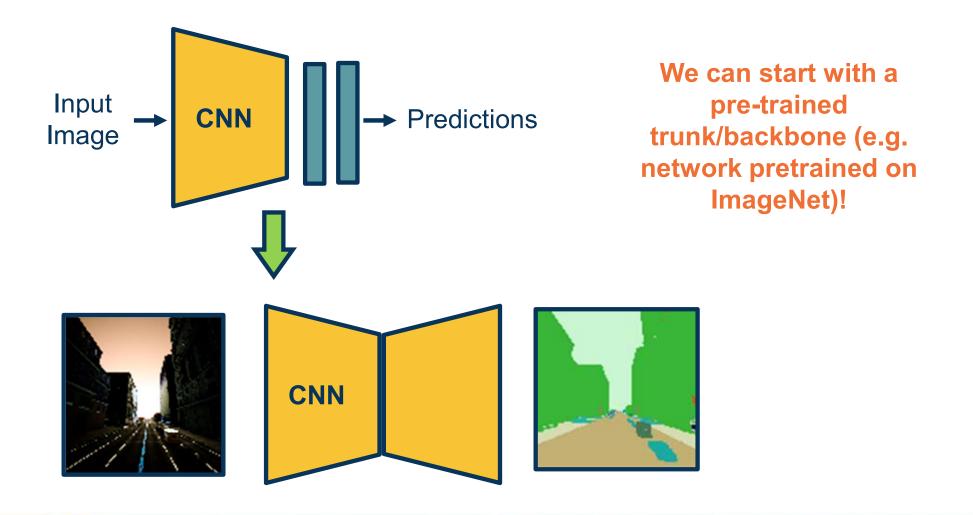

**Transposed Convolution Example** 

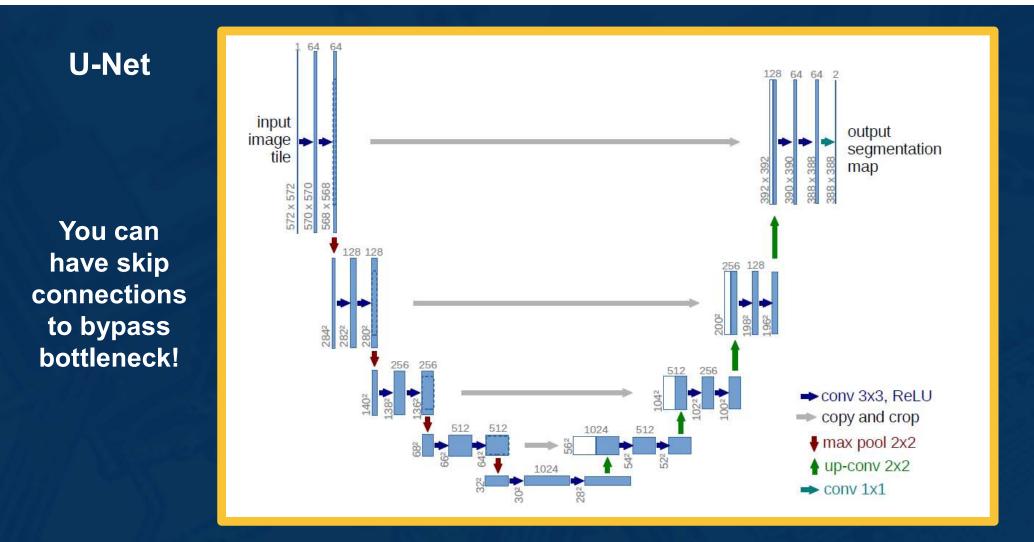

Symmetry in Encoder/Decoder

Ronneberger, et al., "U-Net: Convolutional Networks for Biomedical Image Segmentation", 2015

## Summary

- Various ways to get image-like outputs, for example to predict segmentations of input images
- Fully convolutional layers essentially apply the striding idea to the output classifiers, supporting arbitrary input sizes
  - (without output size depending on what the input size is)
- We can have various upsampling layers that actually increase the size
- Encoder/decoder architectures are popular ways to leverage these to perform general image-to-image tasks

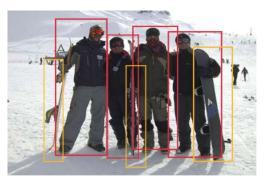

## Single-Stage Object Detection

# Given an image, output a list of bounding boxes with probability distribution over classes per box

Problems:

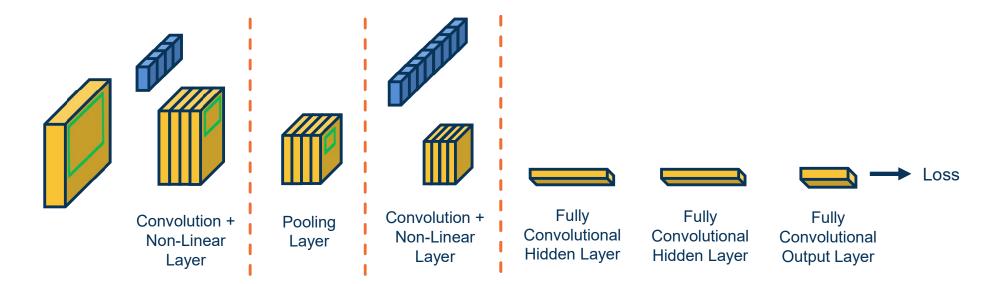

- Variable number of boxes!
- Need to determine candidate regions (position and scale) first

**Object Detection** (List of bounding boxes with class distribution per box)

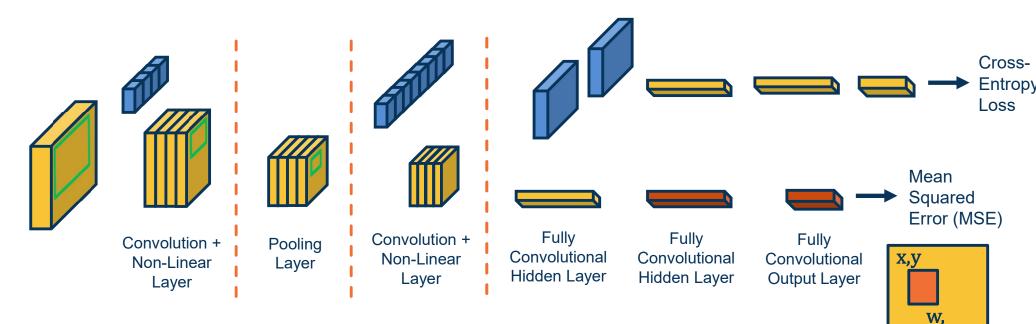

## We can use the same idea of fully-convolutional networks

- Use ImageNet pre-trained model as backbone (e.g. taking in 224x224 image)
- Feed in larger image and get classifications for different windows in image

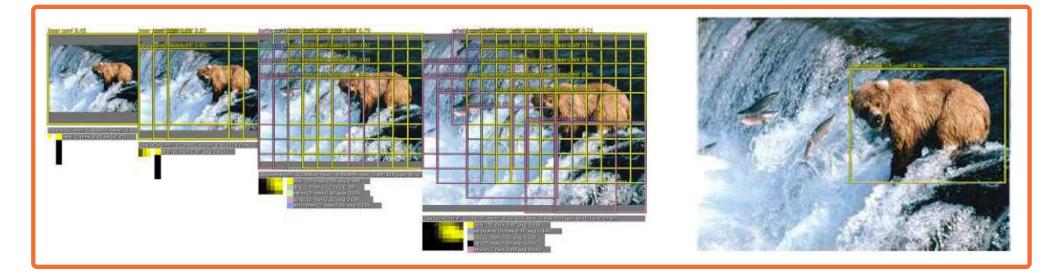

### We can have a multi-headed architecture

- One part predicting distribution over class labels (classification)
- One part predicting a bounding box for each image region (regression)
  - Refinement to fit the object better (outputs 4 numbers)
- Both heads **share features**! Jointly optimized (summing gradients)

## **Object Detection Tasks**

Can also do this at multiple scales to result in a large number of detections

- Various tricks used to increase the resolution (decrease subsampling ratio)
- Redundant boxes are combined through Non-Maximal Suppression (NMS)

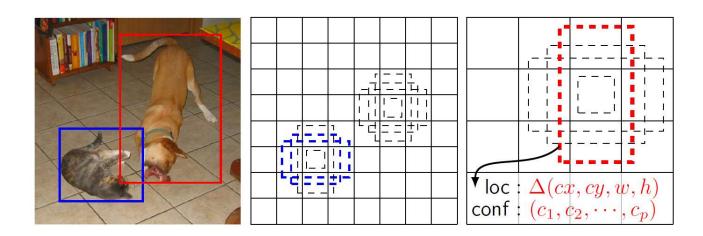

Sermanet, et al., "OverFeat: Integrated Recognition, Localization and Detection using Convolutional Networks", 2013

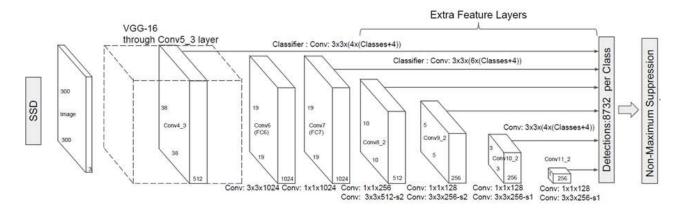

**Object Detection Tasks** 

## Single-shot detectors use a similar idea of **grids** as anchors, with different scales and aspect ratios around them

 Various tricks used to increase the resolution (decrease subsampling ratio)

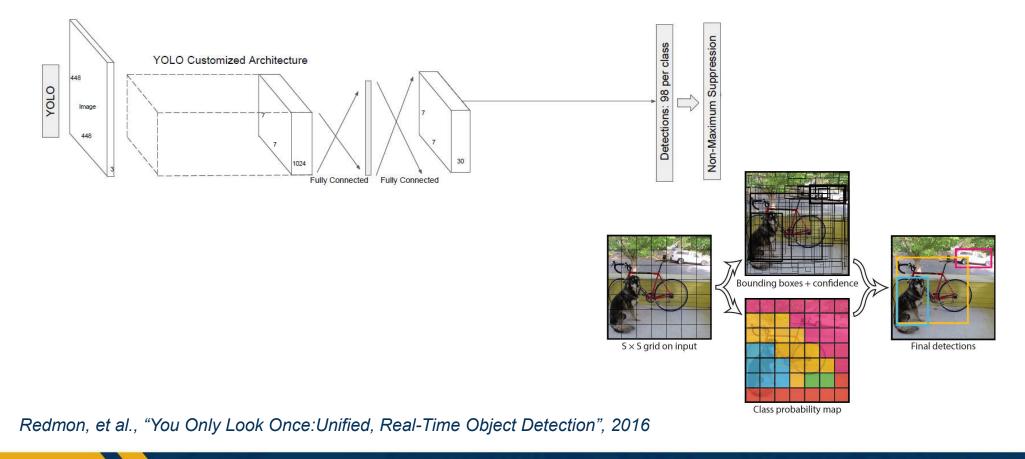

Liu, et al., "SSD: Single Shot MultiBox Detector", 2015

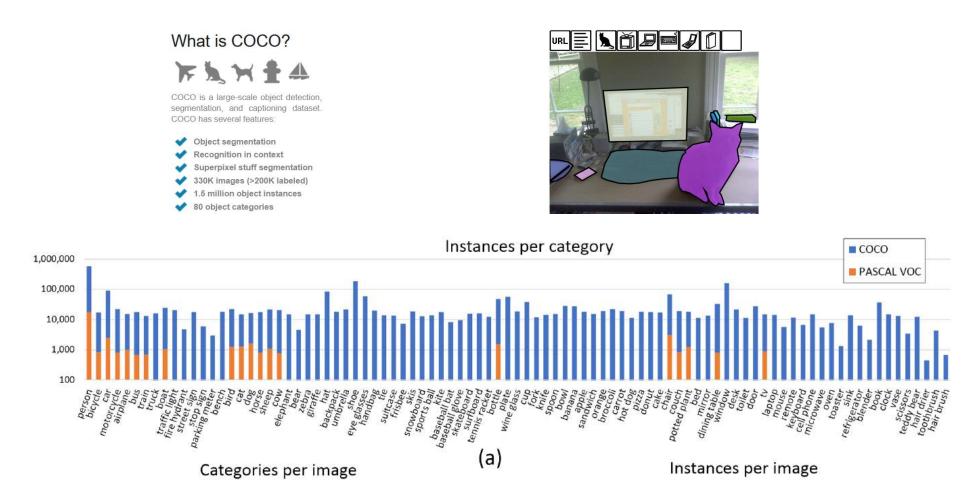

Single-Shot Detector (SSD)

## Similar network architecture but single-scale (and hence faster for same size)

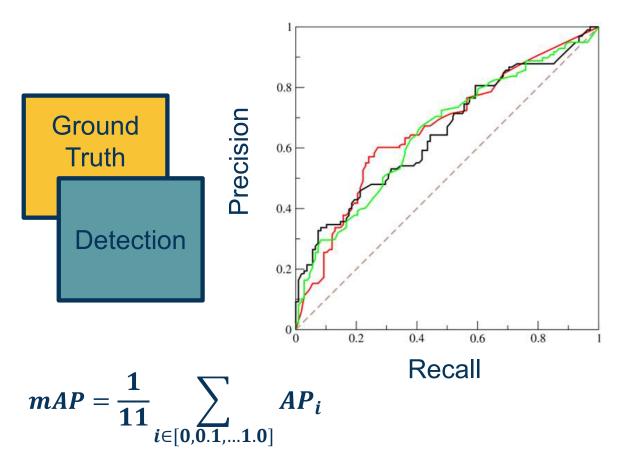

Lin, et al., "Microsoft COCO: Common Objects in Context", 2015. https://cocodataset.org/#explore

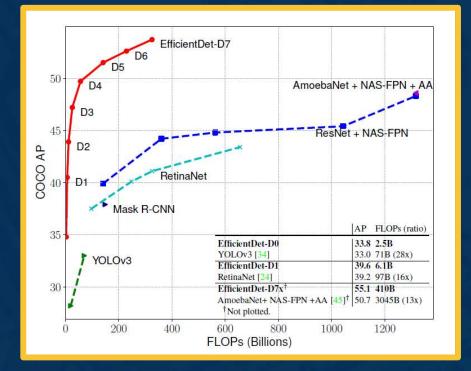

- For each bounding box, calculate intersection over union (IoU)
- 2. Keep only those with IoU > threshold (e.g. 0.5)
- 3. Calculate precision/recall curve across classification probability threshold
- 4. Calculate average precision (AP) over recall of [0, 0.1, 0.2, ..., 1.0]

 Average over all categories to get mean Average Precision (mAP)

## **Evaluation – Mean Average Precision (mAP)**

## **Results**

#### EfficientDet

**PP-YOLO** 

*Tan, et al., "EfficientDet: Scalable and Efficient Object Detection", 2020 Long et al., "PP-YOLO: An Effective and Efficient Implementation of Object Detector", 2020* 

## Two-Stage Object Detectors

Instead of making dense predictions across an image, we can decompose the problem:

• Find regions of interest (ROIs) with object-like things

**R-CNN** 

Classifier those regions (and refine their bounding boxes)

Girshick, et al., "Rich feature hierarchies for accurate object detection and semantic segmentation", 2014

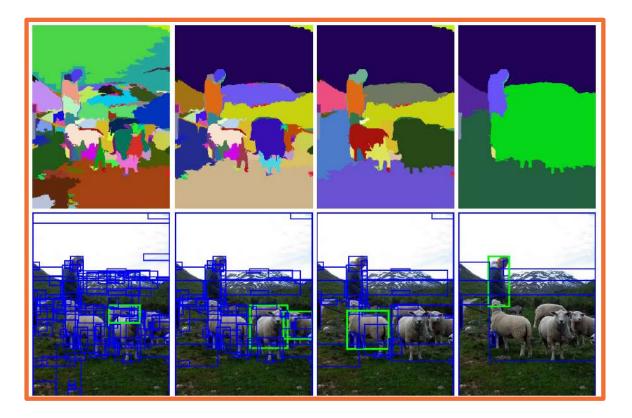

## We can use **unsupervised** (non-learned!) algorithms for finding candidates

## **Downsides:**

- Takes 1+ second per image
- Return thousands of (mostly background) boxes

**Resize each candidate** to full input size and classify

Uijlings, et al., "Selective Search for Object Recognition", 2012

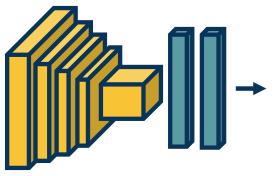

**Extracting Region Proposal** 

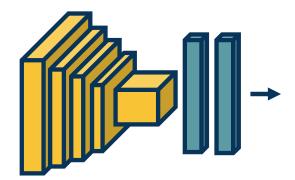

## What is the problem with this?

Computation for convolutions re-done for each image patch, even if overlapping!

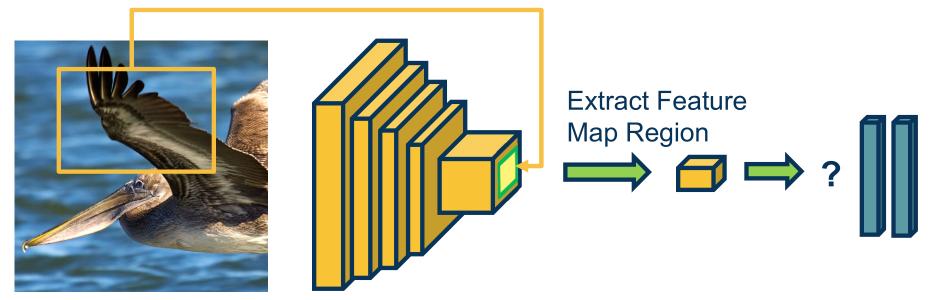

Girshick, et al., "Rich feature hierarchies for accurate object detection and semantic segmentation", 2014

**Inefficiency of R-CNN** 

## Map each ROI in image to corresponding region in feature maps

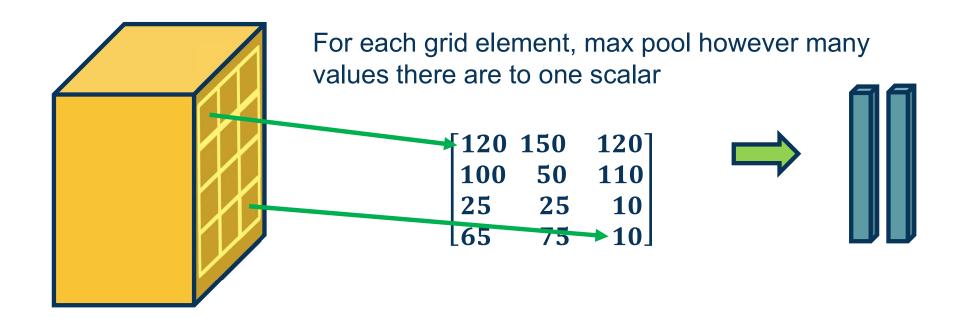

Idea: Reuse computation by finding regions in feature maps

- Feature extraction only done once per image now!
- Problem: Variable input size to FC layers (different feature map sizes)

Girshick, "Fast R-CNN", 2015

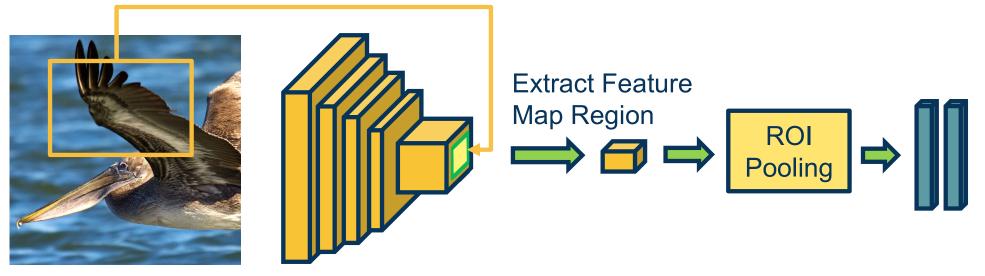

Given an arbitrarily-sized feature map, we can use **pooling** across a grid (ROI Pooling Layer) to convert to fixed-sized representation

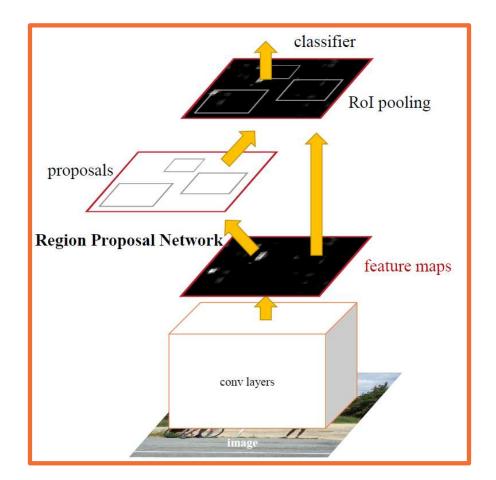

## Map each ROI in image to corresponding are in feature maps

We can now train this model **end-to-end** (i.e. backpropagate through entire model including ROI Pooling)!

- Idea: Why not have the neural network also generate the proposals?
  - Region Proposal Network (RPN) uses same features!
- Outputs objectness score and bounding box
- Top k selected for classification
- Note some parts (gradient w.r.t. bounding box coordinates) not differentiable so some complexity in implementation

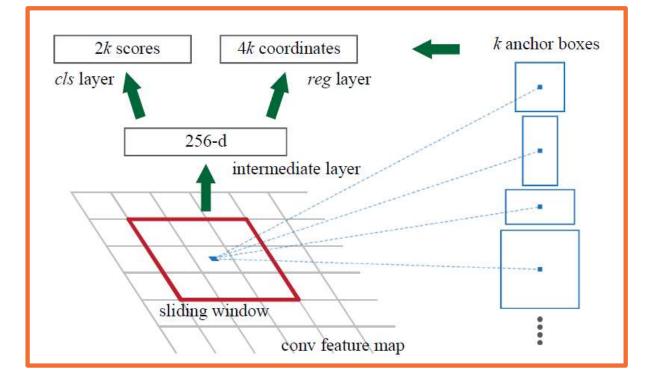

Ren, et al., "Faster R-CNN: Towards Real-Time Object Detection with Region Proposal Networks", 2016

# **RPN** also uses notion of **anchors in a grid**

Boxes of various sizes and scales classified with objectness score and refined bounding boxes refined

Ren, et al., "Faster R-CNN: Towards Real-Time Object Detection with Region Proposal Networks", 2016

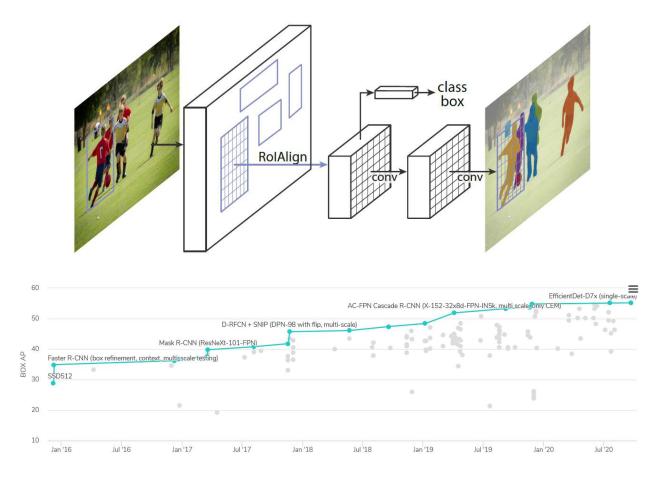

Many new advancements have been made

For example, combining detection and segmentation

Extract foreground (object) mask per bounding box

He, et al., "Mask R-CNN", 2018

https://paperswithcode.com/sota/object-detection-on-coco

- A range of problems characterized by density and type of output
- Semantic/instance segmentation: Dense, spatial output
  - Leverage encoder/decoder architectures
- **Object detection:** Variable-length list of objects
  - Two-stage versus one-stage architectures
  - (Not covered): Anchor-based versus anchor-free methods

# **Bias & Fairness** FACEBOOK AI Georg

# **ML** and Fairness

- Al effects our lives in many ways
- Widespread algorithms with many small interactions
  - e.g. search, recommendations, social media
- Specialized algorithms with fewer but higher-stakes interactions
  - e.g. medicine, criminal justice, finance
- At this level of impact, algorithms can have unintended consequences
- Low classification error is not enough, need fairness

# Amazon scraps secret AI recruiting tool that showed bias against women

Jeffrey Dastin

8 MIN READ

SAN FRANCISCO (Reuters) - Amazon.com Inc's (AMZN.O) machine-learning specialists uncovered a big problem: their new recruiting engine did not like women.

The team had been building computer programs since 2014 to review job applicants' resumes with the aim of mechanizing the search for top talent, five people familiar with the effort told Reuters.

Automation has been key to Amazon's e-commerce dominance, be it inside warehouses or driving pricing decisions. The company's experimental hiring tool used artificial intelligence to give job candidates scores ranging from one to five stars - much like

### **ML and Fairness**

- Fairness is morally and legally motivated
- Takes many forms
- Criminal justice: recidivism algorithms (COMPAS)
  - Predicting if a defendant should receive bail
  - Unbalanced false positive rates: more likely to wrongly deny a black person bail
    Table 1: ProPublica Analysis of COMPAS Algorithm

	White	Black
Wrongly Labeled High-Risk	23.5%	44.9%
Wrongly Labeled Low-Risk	47.7%	28.0%

https://www.propublica.org/article/ machine-bias-risk-assessments-in-criminal-sentencing

## Why Fairness is Hard

- Suppose we are a bank trying to fairly decide who should get a loan
  - i.e. Who is most likely to pay us back?
- Suppose we have two groups, A and B (the sensitive attribute)
  - This is where discrimination could occur
- The simplest approach is to remove the sensitive attribute from the data so that our classier doesn't know the sensitive attribute from the data so that our classier doesn't Table 2: To Loan or Not to Loan?

Age	Gender	Postal Code	Req Amt	A or B?	Pay
46	F	M5E	\$300	A	1
24	M	M4C	\$1000	В	1
33	M	M3H	\$250	А	1
34	F	M9C	\$2000	A	0
71	F	M3B	\$200	A	0
28	М	M5W	\$1500	В	0

### Why Fairness is Hard

- However, if the sensitive attribute is correlated with the other attributes, this isn't good enough
- It is easy to predict race if you have lots of other information (e.g. home address, spending patterns)
- More advanced approaches are necessary

Table 3: To Loan or Not to Loan? (masked)

Age	Gender	Postal Code	Req Amt	A or B?	Pay
46	F	M5E	\$300	?	1
24	М	M4C	\$1000	?	1
33	М	МЗН	\$250	?	1
34	F	M9C	\$2000	?	0
71	F	M3B	\$200	?	0
28	М	M5W	\$1500	?	0

#### Definitions of Fairness – Group Fairness

- So we've built our classier . . . how do we know if we're being fair?
- One metric is demographic parity | requiring that the same percentage of A and B receive loans
  - What if 80% of A is likely to repay, but only 60% of B is?
  - Then demographic parity is too strong
- Could require equal false positive/negative rates
  - When we make an error, the direction of that error is equally likely for both groups

P(loan|no repay, A) = P(loan|no repay, B)P(no loan|would repay, A) = P(no loan|would repay, B)

- These are definitions of group fairness
- Treat different groups equally"

#### Definitions of Fairness – Individual Fairness

- Also can talk about individual fairness | "Treat similar examples similarly"
- Learn fair representations
  - Useful for classification, not for (unfair) discrimination
  - Related to domain adaptation
  - Generative modelling/adversarial approaches

(a) Unfair representations

(b) Fair(er) representations

Figure 1: "The Variational Fair Autoencoder" (Louizos et al., 2016)

#### Conclusion

- This is an exciting field, quickly developing
- Central definitions still up in the air
- AI moves fast | lots of (currently unchecked) power
- Law/policy will one day catch up with technology
- Those who work with AI should be ready
  - Think about implications of what you develop!

# **Calibration**

#### Calibration

- Definition
- Measuring Calibration
- Calibrating models
- Limitations of Calibration

FACEBOOK AI

Geo

A classifier is **well-calibrated** if the probability of the observations with a given probability score of having a label is equal to the proportion of observations having that label

Example: if a binary classifier gives a score of 0.8 to 100 observations, then 80 of them should be in the positive class

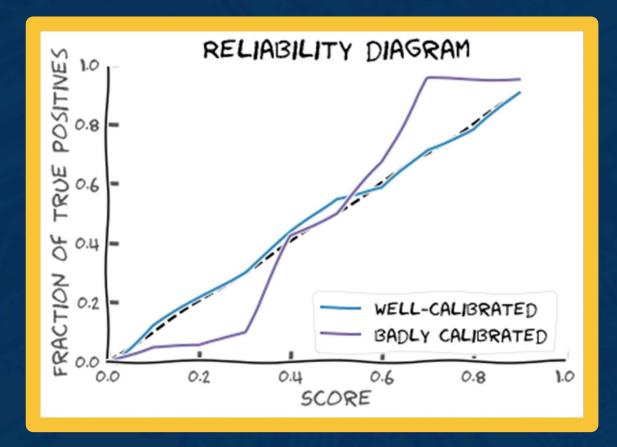

$$\forall p \in [0,1], P(\hat{Y} = Y | \hat{P} = p) = p$$

where  $\widehat{Y}$  is the predicted label and  $\widehat{P}$  is the predicted probability (or score) for class *Y* 

FACEBOOK AI Georgia

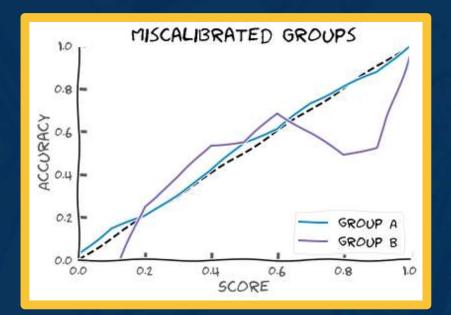

#### **Calibration: Definition**

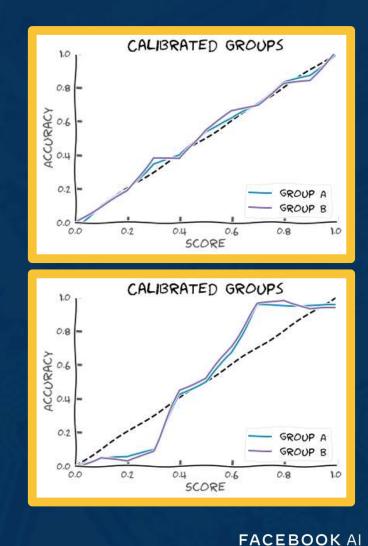

#### **Calibration: Definition**

**Group Calibration:** the scores for subgroups of interest are calibrated (or at least, equally mis-calibrated)

Georgia ≬ Tech ≬

- Some models (e.g Logistic Regression) tend to have well-calibrated predictions
- Some DL models (e.g. ResNet) tend to be overconfident (https://arxiv.org/pdf/1706.04599.pdf)
- Logistic calibration/Platt scaling

**Calibrating a DL Model** 

FACEBOOK AI Ge

# Post-processing approach requiring an additional validation dataset

#### Platt scaling (binary classifier)

• Learn parameters a, b so that the **calibrated probability** is  $\hat{q}_i = \sigma(az_i + b)$  where  $z_i$  is the network's logit output)

Temperature scaling extends this to multi-class classification

• Learn a temperature *T*, and produce calibrated probabilities  $\hat{q}_i = \max_k \sigma_{SoftMax}(z_i/T)$ 

#### **Calibration: Limitations**
