Cindy Xiang Baofish

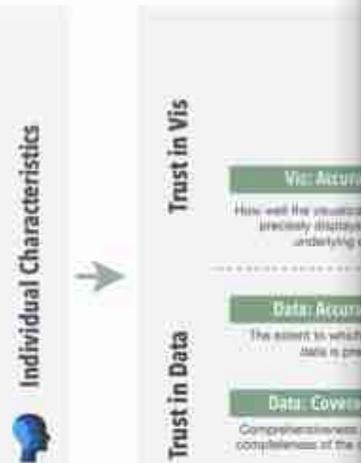

Designing a visualization involves a series of decisions, and each design decision can afford different interpretations.

### Polarizing Political Polls: How Visualization Design Choices Can Shape Public Opinion and Increase Political Polarization

### Vistrust: a Multidimensional Framework and Empirical Study

Hamza Elhamdadi, Adam Smith

### Using Processing Fluency as a Metric of Trust in Scatterplot Visualizations

Fig. 1. We compared people's trust in visualization. The above examples show two different visualizations.

**Abstract**—Establishing trust in a visualization (i.e., how trustworthy a visualization is) is a complex task. Psychology and behavioral science suggest that trust in a visualization is influenced by two empirical factors: processing fluency and processing fluency. Participants estimate non-camouflaged control; they produced less accurate estimates adapted from behavioral economic models.

### A Design Space of Vision Science Methods for Visualization Research

### My Model is Unfair, Do People Even Care? Visual Design Affects Trust and Perceived Bias in Machine Learning

Aimen Gaba, Zhianna Kautzman, Jason Cheung, Maria Shweid, Hye Yhin, Hail, Yury Buz, and Cindy Xiang Baofish

**Abstract**—Machine learning technology has become ubiquitous, but, unfortunately, often produces bias. As a consequence, disparate stakeholders need to interact with and make informed decisions about using machine learning models in everyday systems. Visualization technology can support stakeholders in understanding and evaluating trade-offs between, for example, accuracy and fairness of models. This paper aims to empirically answer "Can visualization design choices affect a stakeholder's perception of model bias, trust in a model, and willingness to adopt a model?" Through a series of controlled, user-centered experiments with more than 1,000 participants, we identify a set of strategies people adopt in deciding which model to trust. Our results show that men and women perceive fairness and performance differently and that visual design choices significantly affect the perception. For example, women trust facial models more often than men do; participants trust facial models more when it is explained using bar charts and being explicitly told a model is biased has a bigger impact than showing past biased performance. We test the generalizability of our results by comparing the effect of multiple textual and visual design choices and offer potential applications of the cognitive mechanisms behind the differences in fairness perception and trust. Our research guides design practitioners to support future work designing visualization systems for machine learning.

**Index Terms**—machine learning, fairness, bias, trust, visual design, gender, human-subject studies
