Recap

## External Merge Sort

－Divide－and－conquer sorting algorithm that splits the data set into separate runs and then sorts them individually．
－Phase 1 －Sorting
－Sort blocks of data that fit in main－memory and then write back the sorted blocks to a file on disk．
－Phase 2 －Merging
－Combine sorted sub－files into a single larger file．

## Aggregation

- Collapse multiple tuples into a single scalar value.
- Two implementation choices:

Sorting
Hashing

## Hashing Aggregate

## in－rremong

－Populate an ephemeral hash table as the DBMS scans the table．
－For each record，check whether there is already an entry in the hash table：
－GROUP BY：Perform aggregate computation．
－DISTINCT：Discard duplicates．
－Ifeverything fits in memory，then it is easy．
－If the DBMS must spill data to disk，then we need to be smarter．

Today's Agenda
$\Gamma_{0}$ Overview

- Nested Loop Join

Sort-Merge Join

- Hash Join
]

## Overview

## Why do we need to join？

－We normalize tables in a relational database to avoid unnecessary repetition of information．
－We use the join operator to reconstruct the original tuples without any information loss．

## Denormalized Tables

| Artists | ID | Artist | Year | City |
| :---: | :---: | :---: | :---: | :---: |
|  | 1 | Mozart | 1756 | Salzburg |
|  | 2 | Beethoven | 1770 | Bonn |

|  | ID | Album | Artist | Year |
| :--- | :--- | :--- | :--- | :--- |
| Albums | 1 | The Marriage of Figaro | Mozart | 1786 |
|  | 2 | Requiem Mass In D minor | Mozart | 1791 |
|  | 3 | Für Elise | Beethoven | 1867 |

## Normalized Tables

Artists（ID，Artist，Year，City）
Albums（ID，Album，Year）
ArtistAlbum（Artist＿ID，Album＿ID）

| ArtistAlbum | Artist＿ID | Album＿ID |
| :--- | :--- | :--- |
|  | 1 | 1 |
|  | 2 | 1 |
|  | 2 | 2 |

## Join Algorithms

- We will focus on combining two tables at a time with inner equi-join glgorithms.
- These algorithms can be tweaked to support other types of joins.
- In general, we want the smaller table to always be the left table (outer table) in the query plan.

## Join Operators

- Decision 1: Output
- What data does the join operator emit to its parent operator in the query plan tree?
- Decision 2: Cost Analysis Criteria
- How do we determine whether one join algorithm is better than another?
SELECT R.id, S.cdate
FROM R JOIN S
ON R.id = S.id

[^0]

## Join Operator Output

- For a tuple $r \in R$ and a tuple $s \in S$ that match on join attributes, concatenate $r$ and $s$ together into a new tuple.
- Contents can vary:

Depends on query processing model
Depends on storage model
Depends on the query

## Join Operator Output: Data

- Copy the values for the attributes in outer and inner tuples into a new output tuple.
- Subsequent operators in the query plan never need to go back to the base tables to get more data.

matrisiciontion

## Join Operator Output: Record Ids

- Only copy the joins keys along with the record ids of the matching tuples.
- Ideal for column stores because the DBMS does not copy data that is not need for the query.
- This is called late materialization.

## I/O Cost Analysis

Assume: Dams

- M pages in table R, $m$ tuples in $R$ Npages in table $\underline{S}, n$ tuple fins
- Cost Metric: Number 51 IO operations to compute join
- We will ignore output costs (since that depends on the data and we cannot compute that yet).

SELECT R.id, S.cdate FROM R JOIN S

ON R.id = Sid WHERE S. value > 100

## Join vs Cross-Product

- $\mathrm{R} \bowtie \mathrm{S}$ is the most common operation and thus must be carefully optimized.
- $\widehat{\mathrm{R} \times \mathrm{S}}$ followed by a selection is inefficient because the cross-product is large.
- There are many algorithms for reducing join cost, but no algorithm works well in all scenarios.

## Join Algorithms

－Nested Loop Join
Naïve Block

Sort－Merge Join
－Hash Join

## Nested Loop Join

## Nested Loop Join

```
R (id, name) S (id, value, cdate)
```

operator NestedLoopJoin $(R, S)$ :
for each tuple $r \in R: / /$ Outer Table for each tuple $s \in S: / /$ Inner Table emit, if $r$ and $s$ match

## Naïve Nested Loop Join

－Why is this algorithm naïve？
－For every tuple in $\underline{\mathbf{R}}$ ，it scans $\underline{\mathbf{S}}$ once
－R：M pages，m tuples
－ $\mathrm{S}: \mathrm{N}$ pages， n tuples
－Cost： $\mathrm{M}+(\mathrm{m} \times \mathrm{N})$

Naïve Nested Loop Join

- Fxanaple Database:
- Table R: M = 1000 pages, $m=100,000$ tuples
- Table S: $\mathrm{N}=500$ pages, $\mathrm{n}=40,000$ tuples
- Each page $=4 \mathrm{~KB} \Longrightarrow$ Database size $=6 \mathrm{MB}$
- Cost Analysis:
- $\mathrm{M}+(\mathrm{m} \mathrm{\times N})=1000+(100000 \times 500)=50,001,00$ IOs
- At $0.1 \mathrm{~ms} / \mathrm{IO}$, Total time $\approx 1.3$ hours
- What if smaller table (S) is used as the outer table?
- $\mathrm{N}+(\mathrm{n} \times \mathrm{M})=500+(40000 \times 1000)=40,000,500 \mathrm{IOs}$
- At $0.1 \mathrm{~ms} / \mathrm{IO}$, Total time $=1.1$ hours

## Block Nested Loop Join

```
R (id, name)
S (id, value, cdate)
```

operator BlockNestedLoopJoin $(R, S)$ :
for each block $b_{R} \in R$ : // Outer Table for each block $b_{S} \in S$ : // Inner Table for each tuple $r \in b_{R}$ :
for each tuple $s \in b_{S}$ :
emit, if $r$ and $s$ match

Block Nested Loop Join

$$
\begin{array}{ll}
4 \forall B \\
N B & m \gg 0
\end{array}
$$

- This algorithm performs fewer disk accesses.
- For every block in R, it scans $S$ once
- Cost: $\mathrm{M}+(\mathrm{M} \times \mathrm{N})$

$$
\begin{aligned}
& M+(m \times N) \\
& M+(m \times N)
\end{aligned}
$$

## Block Nested Loop Join

- Which one should be the outer table?
- The smaller table in terms of number of pages

## Block Nested Loop Join

- Example Database:
- Table R: M = 1000 pages, $m=100,000$ tuples
- Table S: $\mathrm{N}=500$ pages, $\mathrm{n}=40,000$ tuples
- Cost Analysis:
- $\mathrm{M}+(\mathrm{M} \times \mathrm{N})=1000+(1000 \times 500)=501,000$ IOs
- At $0.1 \mathrm{~ms} / \mathrm{IO}$, Total time $\approx 50$ seconds

External Block Nested Loop Join

## Block Nested Loop Join

- This algorithm uses B-2 buffers for scanning R.
- Cost: $\mathrm{M}+(\lceil\mathrm{M} /(\mathrm{B}-2)\rceil \times \mathrm{N})$
- What if the outer relation completely fits in memory (i.e., $\mathrm{B}-2>\mathrm{M}$ )?
- Cost: $\mathrm{M}+\mathrm{N}=1000+500=1500$ IOs
- At $0.1 \mathrm{~ms} / \mathrm{IO}$, Total time $\approx 0.15$ seconds

## Nested Loop Join

- Why do basic nested loop joins suck?
- For each tuple in the outer table, we must do a sequential scan to check for a match in the inner table.
- We can avoid sequential scans by using an index to find inner table matches.
- Use an existing index for the join.
- Or build an index on the fly (e.g., hash table, B+Tree).

## Index Nested Loop Join

60

R (id, namıe)
S (id value, cuiate)
Index on $S$ (id)
operator IndexNestedLoopJoin $(R, S)$ :
for each tuple $r \in R$ : // Outer Table for each tuple $s \in \operatorname{Index}\left(r_{i}=s_{i}\right)$ : // Index on Inner Table
 emit, if $r$ and $s$ match

## Index Nested Loop Join

－Assume the cost of each index probe is some constant $C$ per tuple．
－Cost： $\mathrm{M}+(\mathrm{m} \times \mathrm{C})$

find

## Summary

－Pick the smaller table as the outer table．
－Buffer as much of the outer table in memory as possible．
－Loop over the inner table or use an index if available．

## Sort-Merge Join

## Sort－Merge Join

## －Phase 1：Sort

－Sort both tables on the join key（s）．
－Phase 2：Merge

－We can then use the external merge sort algorithm to join the sorted tables．
－Step through the two sorted tables with cursors and emit matching tuples．
－May need to backtrack depending on the join type．

## Sort-Merge Join

R (id, name)
S (id, value, cdate)
operator SortMergeJoin (B/S): sort R,S on join keys/
 else if cursor $_{R}$ and cursorS match: emit increment cursors
 cursor $_{R} \leftarrow R_{\text {sorted, }}$ cursorS $\leftarrow S_{\text {sorted }}$ while cursor ${ }_{R}$ and cursorS:
if cursor ${ }_{R}>$ cursorS: increment cursorS
else if cursor $_{R}<$ cursorS: increment cursorR

Sort－Merge Join

Sort-Merge Join

External May Sos

- $\operatorname{Sort} \operatorname{Cost}(\underline{\mathbf{R}}): 2 \mathrm{Mx}\left(1+\left\lceil\log _{\mathrm{B}-1}\lceil\mathrm{M} / \mathrm{B}\rceil\right\rceil\right)$
- Sort Cost (S): $2 \mathrm{~N} \times\left(1+\left\lceil\log _{\mathrm{B}-1}\lceil\mathrm{~N} / \mathrm{B}\rceil\right\rceil\right)$
- Merge Cost: $\left(\mathrm{M}^{\circ}+\mathrm{N}\right)$
- Total Cost: Sort + Merge $\operatorname{Tos}^{A}\left[\left(\frac{T}{B}\right]\right)$

$$
=\int_{\beta-1} 1+\operatorname{los}_{\beta-1}
$$

## Sort-Merge Join

- Example Database:
$\Longrightarrow$ Table R: $\mathrm{M}=1000$ pages, $\mathrm{m}=100,000$ tuples
$\rightarrow$ Table S: $\mathrm{N}=500$ pages, $\mathrm{n}=40,000$ tuples
- With $B=100$ buffer pages, both $R$ and $S$ can be sorted in two passes:
( Sort Cost (R) $=2000 \times\left(1+\left\lceil\log _{99} 1000 / 100\right\rceil\right)=4000 \mathrm{IOs}$
Sort Cost $(S)=1000 \times\left(\overline{\left.1+\mid \log _{99} 500 / 100\right\rceil}\right)=2000$ IOs
Merge Cost $=(1000+500)=1500$ IOs
- Total Cost $=4000+2000+(1500)=7500 \mathrm{IOs}$
- At $0.1 \mathrm{~ms} / \mathrm{IO}$, Total time $\approx 0.75$ seconds

0.155
(merg )

Sort－Merge Join

1

$$
\text { Worst } 1 \text { Crt }
$$

－The worst case for the merging phase is when the join attribute of all of the tuples in both relations contain the same value．
－Cost：$(\mathrm{M} \times \mathrm{N})+($ sort cost $)$

$$
\begin{gathered}
\text { seluticion } \\
\text { suasion } \\
\hline 1.0
\end{gathered}
$$

## When is Sort-Merge Join Useful?

- One or both tables are already sorted on join key.
- Output must be sorted on join key.
- The input relations may be sorted by either by an Explicit sort operator, or by scanning the relation using an index on the join key.

## 

## $\operatorname{rash}(x) \neq \operatorname{hash}(y)$ <br> 

－If tuple $r \in R$ and a tuple $s \in S$ satisfy the join condition，then they have the same value for the join attributes．
－If that value is hashed to some partition $i$ ，the $R$ tuple must be in $r_{i}$ and the $S$ tuple in $s_{i}$ ．
－Therefore，R tuples in $r_{i}$ need only to be compared with $S$ tuples in $s_{i}$ ．

## Basic Hash Join Algorithm

## - Phase 1: Build

- Scan the outer table and populate a hash table using the hash function $h_{1}$ on the join attributes.
- Phase 2: Probe
- Scan the inner table and use $h_{1}$ on each tuple to jump to a location in the hash table and find a matching duple.

## Basic Hash Join Algorithm

```
R (id, name)
S (id, value, cdate)
```

operator BasicHashJoin $(R, S)$ :
build hash table $H T_{R}$ for $R$
for each tuple $s \in S$
emit, if $h_{1}(s)$ in $H T_{R}$

Basic Hash Join Algorithm

pid $>$ Sid

## Hash Table Contents

Key: The attribute(s) that the query is joining the tables on.
Value: Depends on what the parent operator above the join in the query plan expects as its input.

- Approach 1: Full Tuple
- Avoid having to retrieve the outer table's tuple contents on a match.
- Takes up more space in memory.
- Approach 2: Tuple Identifier
- Ideal for column stores because the DBMS does not fetch data from disk unless needed.
- Also better if join selectivity is low.

## Probe Phase Optimization

－Create bloom filter during the build phase when the key is likely to not exist in the hash table．
－Threads check the filter before probing the hash table．
－This will be faster since the filter will fit in CPU caches．
－a．k．a．，sideways information passing．

Probe Phase Optimization

## Hash Join

- What happens if we do not have enough memory to fit the entire hash table?
- We do not want to let the buffer pool manager swap out the hash table pages randomly.

## Grace Hash Join

- Hash join when tables do not fit in memory.
- Build Phase: Hash both tables on the join attribute into partitions.
- Probe Phase: Compares tuples in corresponding partitions for each table.
- Named after the

GRACE database machine from Japan in the 1980s.

GRACE University of Tokyo

## Grace Hash Join

－Hash $\underline{\mathbf{R}}$ into（ $0,1, \ldots$, max $)$ buckets．
－Hash $\underline{\mathbf{S}}$ into the same number of buckets with the same hash function．
－Join each pair of matching buckets between $R$ and $S$ ．

Grace Hash Join

Grace Hash Join

Grace Hash Join

- If the bucket do not fit in memory, then use recursive partitioning o split the tables into eतtunks that will fit.
- Build another hash table for bucket ${ }_{R, i}$ using hash function $h_{2}$ with $h_{2}!=h_{1}$ ).
- Then probe it for each tuple of the other table's bucket at that level.

## Recursive Partitioning

## Recursive Partitioning

Hash Join
Recursive Partitioning

## Recursive Partitioning

Recursive Partitioning of large bucees

## Grace Hash Join

Partitioning Phase:

- Read+Write both tables
- $2 x(\mathrm{M}+\mathrm{N}) \mathrm{IOs}$

Probing Phase:

- Read both tables
- M + N IOs
- Total Cost: $3 \times(\mathrm{M}+\mathrm{N})$

## Grace Hash Join

－Example Database：
－Table R：M＝ 1000 pages，$m=100,000$ tuples
－Table S： $\mathrm{N}=500$ pages， $\mathrm{n}=40,000$ tuples
－Cost Analysis：
－ $3 \times(\mathrm{M}+\mathrm{N})=3 \times(1000+500)=4,500 \mathrm{IOs}$
－At $0.1 \mathrm{~ms} / \mathrm{IO}$ ，Total time $\approx 0.45$ seconds

## Observation

- If the DBMS knows the size of the outer table, then it can use static hash table. - Less computational overhead for build / probe operations.
- If we do not know the size, then we have to use dynamic hash table gr allow for overflow pages.

## Conclusion

## Join Algorithms：Summary

| Join Algorithm | IO Cost | Example |
| :--- | :--- | :--- |
| Simple Nested Loop Join | $\mathrm{M}+(\mathrm{m} \times \mathrm{N})$ | 1.3 hours |
| Block Nested Loop Join | $\mathrm{M}+(\mathrm{M} \times \mathrm{N})$ | 50 seconds |
| Index Nested Loop Join | $\mathrm{M}+(\mathrm{M} \times \mathrm{C})$ | Variable |
| Sort－Merge Join | $\mathrm{M}+\mathrm{N}+($ sort cost）$)$ | 0.75 seconds |
| Sash Join | $3 \times(\mathrm{M}+\mathrm{N})$ | 0.45 seconds |
|  |  | ． |
|  |  | indiun |

## Conclusion

－Hashing is almost always better than serting for operator execution．
－Caveats：
－Sorting is better on non－uniform data．
－Sorting is better when result needs to be sorted．
－Good DBMSs use either or both．
－Next Class
－Composing operators together to execute queries．

[^0]:    WHERE S.value > 100
