

# ApertureData

Redefining Visual Data Management

[vishakha@aperturedata.io](mailto:vishakha@aperturedata.io)

[www.aperturedata.io](http://www.aperturedata.io)

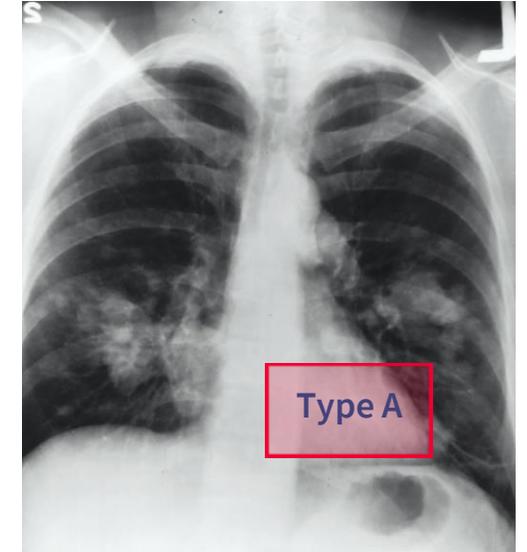

# Explosion in Visual Data Fueled by Data Science

Smart agriculture using drone cameras to determine right soil treatments

People identification using city cameras to determine social distancing

Machine learning on patient scans to help experts diagnose problems

# What's Special About Visual Data Now?

## Large and voluminous

Individual image and video can be GB size and start at millions even for small deployments

## Unique transformations

Basic operations like crop / zoom are common and can be computationally expensive

## Extensive metadata

Not just about visual data itself but application context, annotations, features

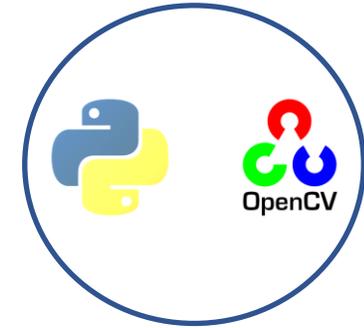

# Today's Visual Applications

Object stores or file systems for image / video data treated as regular blobs

CSV files or some database for metadata, not visual friendly

Stitch libraries for pre-processing before use

Manual integrations result in inefficiencies

# ApertureDB: A Database for Visual Data

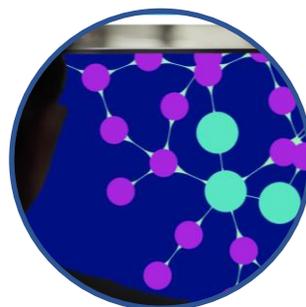

# ApertureDB: Key Features

## Visual Data

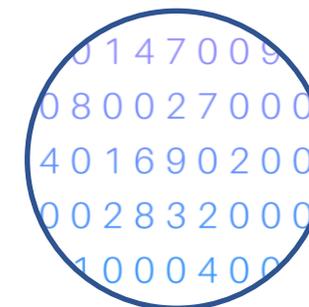

**Native support for images, videos, bounding boxes, and pre-processing operations**

## Metadata

**Metadata information as a knowledge graph for more advanced visual search**

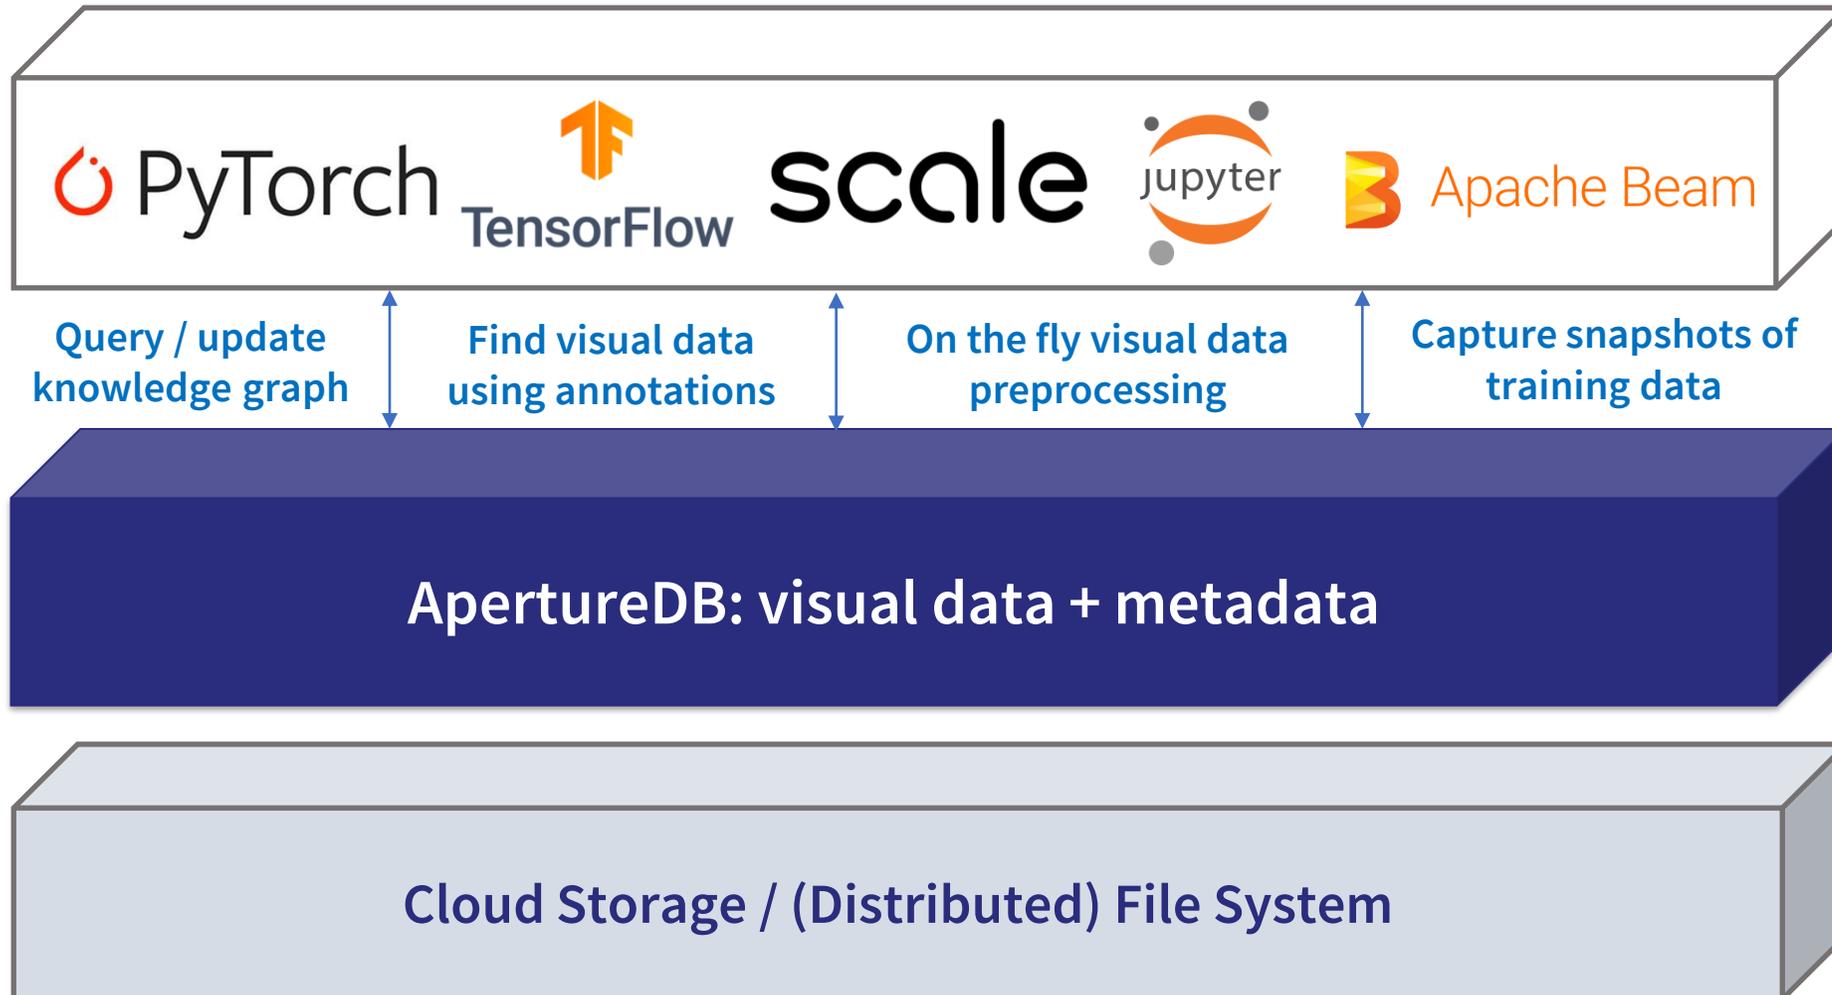

## Similarity Search

**Built-in similarity matching for high-dimensional feature vectors**

# ApertureDB (VDMS) Architecture

# Persistent Memory Graph Database

## Property graph implementation targeting persistent memory (Intel)

- Traditional property graph databases plagued by disk latencies
- NVM technology (e.g. Optane) with performance close to DRAM

ACID with transactional semantics

Easy to evolve schema

Graph API, neighbor traversals, management tools

# Salient Design Features

## PM-aware data layout and access

- Memory-mapped large files from ext4-DAX
- Fix size node and edge objects align with cache size
- clflushopt/clwb or msync for persistence
- Custom allocators
- Lazy iteration

2 level indexes for class and properties, per node edge indexes

Undo logs

Stripe locks and variable concurrency mechanisms

# Visual Compute Module

## Manage actual storage and access of visual objects

- Data on file system or object store
- Implement different formats, pre-processing using OpenCV, ffmpeg when possible
- Perform common operations closer to the data

## Feature vector indexing and similarity search (a la feature db)

- Various indexing techniques (trade-off accuracy and speed)
- Persistent FAISS indexes, TileDB sparse and dense indexes
- K nearest neighbors on n-dimensional feature vectors using different distance metrics
- Graph node which allows filtering with properties after KNN

    }
  }
]
```

# High Performance: Comparing with Status Quo

vs.

- YFCC100M (~100 million images) dataset
- Metadata-based visual search queries to find right set of images
- Up to 35x faster and 15x on average

# Resource Efficient: Preprocessing Near Data

**63%**  
**reduction**

in data transferred over the network  
using pre-processing within our API

# Efficient and Scalable: Biotech AI Customer Use Case

## Save months

Customer saved months of data  
platform engineering  
time

## 1B metadata entities

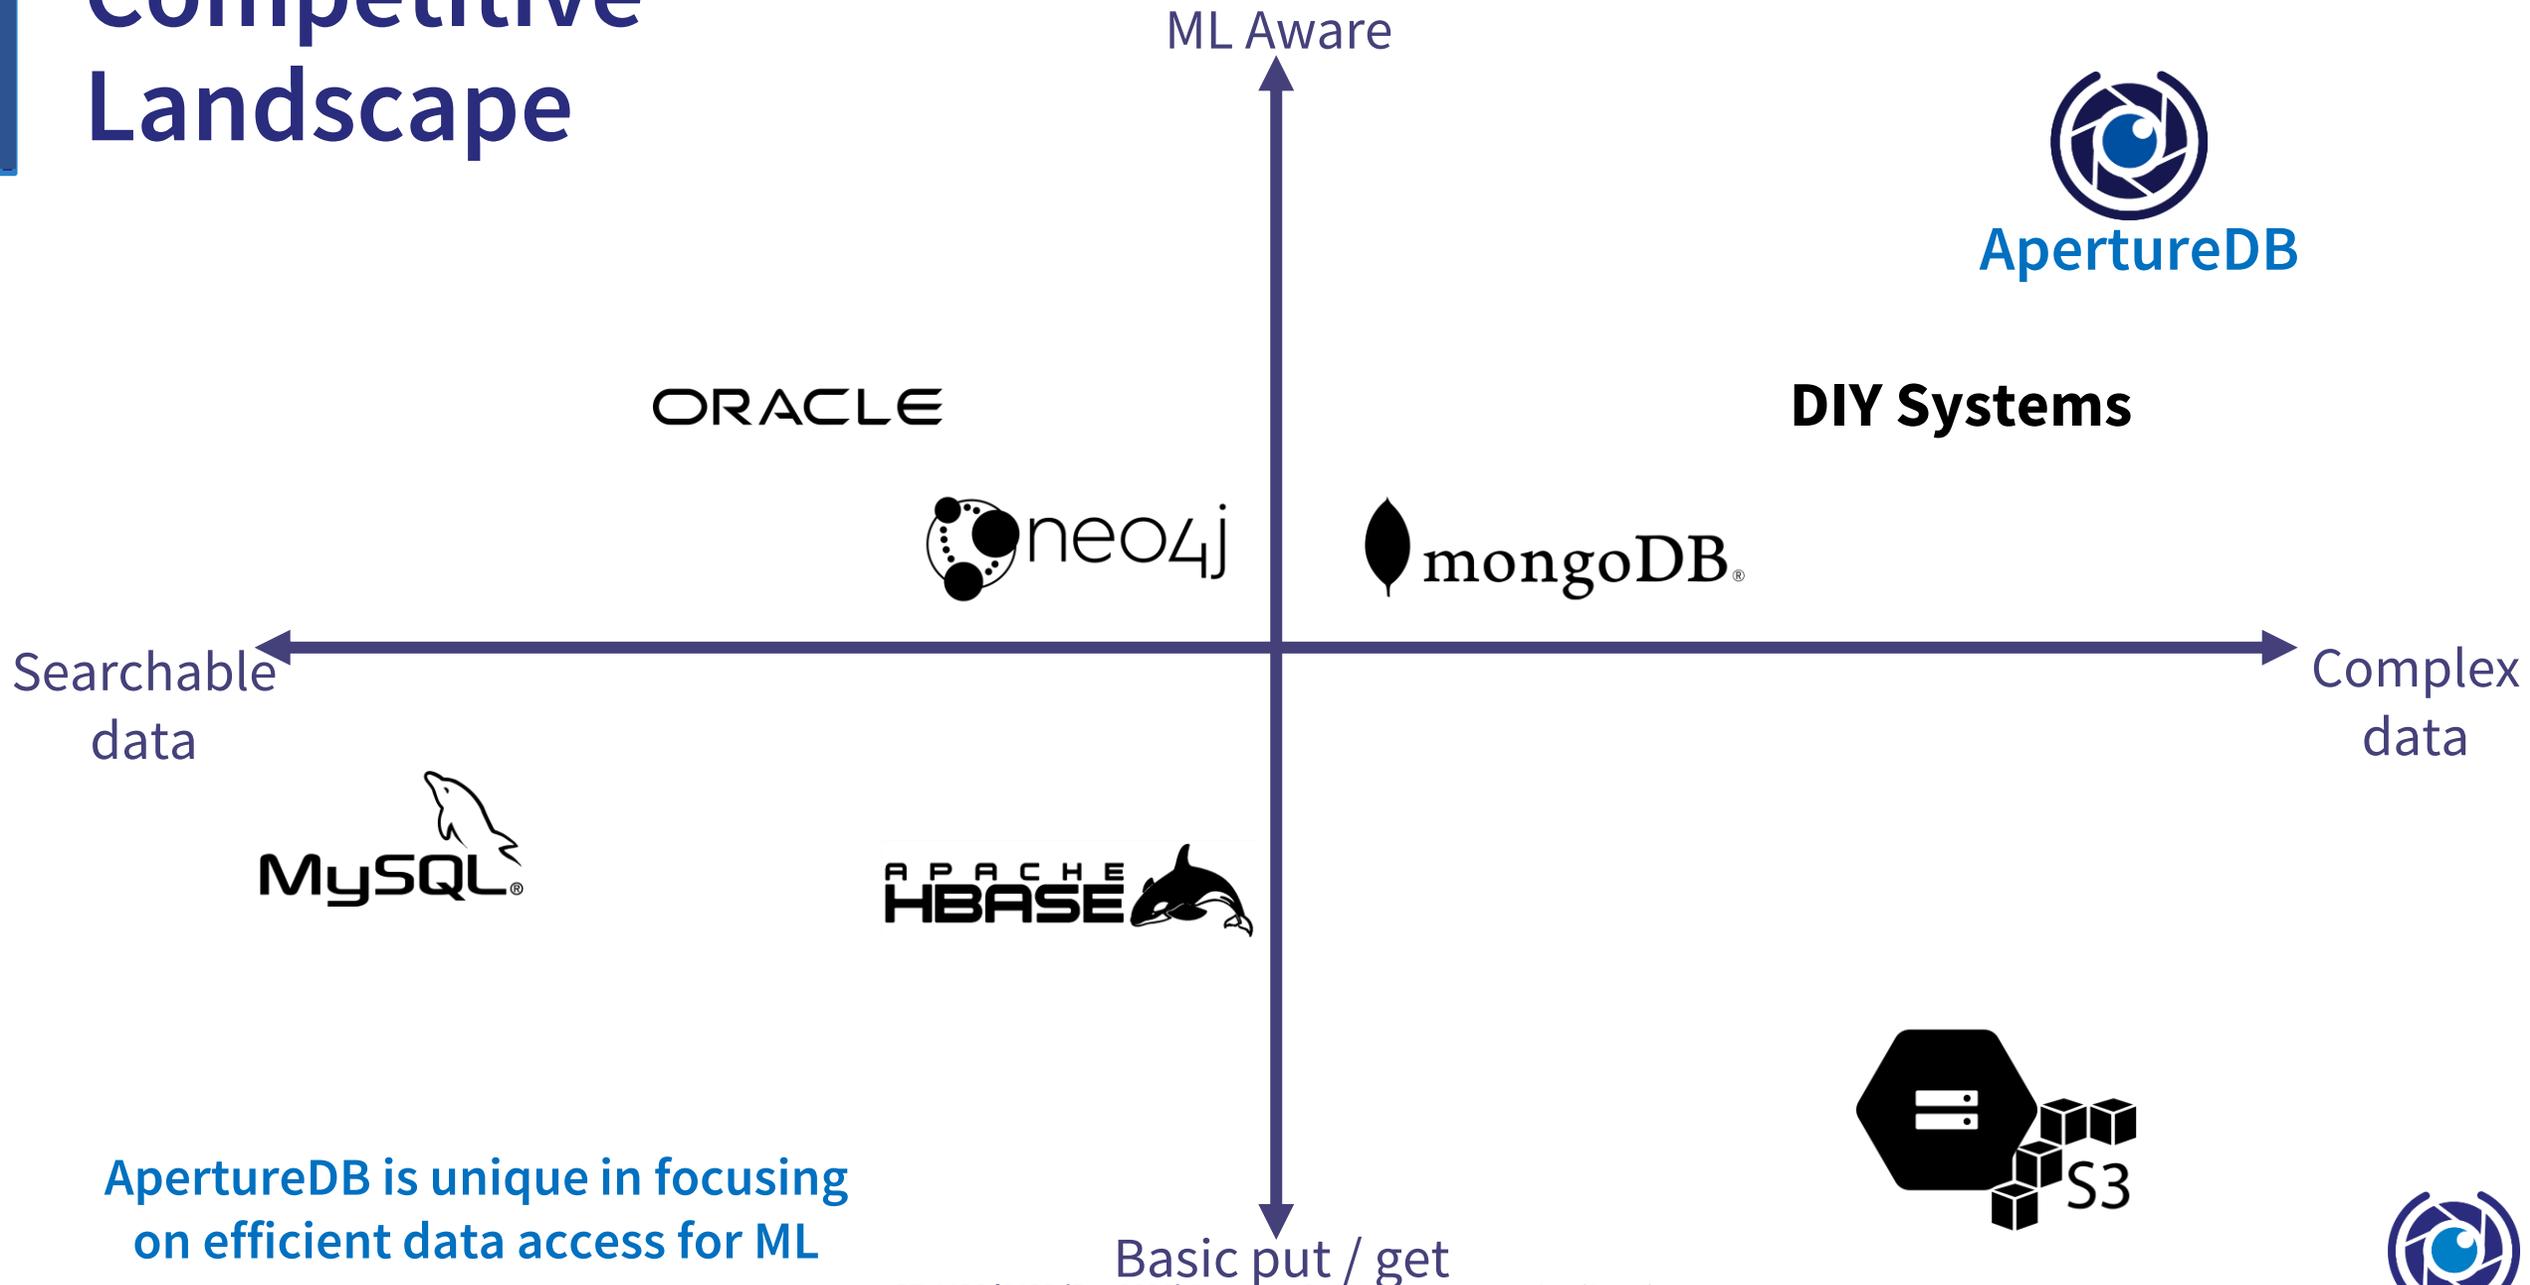

Already loaded over 1B  
metadata entities and  
terabytes of data

## Simpler ML pipeline

Fewer moving parts and  
simplification of a complex ML  
pipeline

# Competitive Landscape

# Near-term Features

More integrations e.g. PyTorch data loader, cloud storage connectors

Increased reliability (data + uptime), debuggability

Advanced UI frontend beyond dataset exploration

User-defined functions

Object model for simpler pipeline interaction

More complex regions of interest e.g. polygons
