Observer Design for Stochastic Nonlinear Systems via Contraction-Based Incremental Stability

Ashwin P. Dani, Member, IEEE, Soon-Jo Chung, Senior Member, IEEE, and Seth Hutchinson, Fellow, IEEE

Abstract—This paper presents a new design approach to nonlinear observers for Itô stochastic nonlinear systems with guaranteed stability. A stochastic contraction lemma is presented which is used to analyze incremental stability of the observer. A bound on the mean-squared distance between the trajectories of original dynamics and the observer dynamics is obtained as a function of the contraction rate and maximum noise intensity. The observer design is based on a non-unique state-dependent coefficient (SDC) form, which parametrizes the nonlinearity in an extended linear form. The observer gain synthesis algorithm, called linear matrix inequality state-dependent algebraic Riccati equation (LMI-SDARE), is presented. The LMI-SDARE uses a convex combination of multiple SDC parametrizations. An optimization problem with state-dependent linear matrix inequality (SDLMI) constraints is formulated to select the coefficients of the convex combination for maximizing the convergence rate and robustness against disturbances. Two variations of LMI-SDARE algorithm are also proposed. One of them named convex state-dependent Riccati equation (CSDRE) uses a chosen convex combination of multiple SDC matrices; and the other named Fixed-SDARE uses constant SDC matrices that are pre-computed by using conservative bounds of the system states while using constant coefficients of the convex combination pre-computed by a convex LMI optimization problem. A connection between contraction analysis and $L_2$ gain of the nonlinear system is established in the presence of noise and disturbances. Results of simulation show superiority of the LMI-SDARE algorithm to the extended Kalman filter (EKF) and state-dependent differential Riccati equation (SDDRE) filter.

I. INTRODUCTION

The present paper is motivated by the fact that the state estimation for many engineering and robotics applications, such as simultaneous localization and mapping (SLAM) [1], [2], has to overcome issues with nonlinearities and stochastic uncertainty. Itô stochastic nonlinear dynamic systems, driven by white noise, exhibit a non-Gaussian probability density, whose time-evolution is characterized by the Fokker-Planck equation—a partial differential equation [3], [4]. Both nonlinearity and non-Gaussian distribution of the probability density of the states make the optimal estimation problem very challenging. A state estimator for nonlinear systems driven by Cauchy noise is presented in [5]. Popular filtering approaches for nonlinear systems include the extended Kalman filter (EKF) [6], the unscented Kalman filter [7], particle filters [8], and the set membership filter [9]. Conventional nonlinear observer designs are based on deterministic nonlinear systems (e.g., Lipschitz nonlinear systems [10], [11], monotone nonlinearities [12], and high gain observers [13]).

The observer design methods based on deterministic systems neglect the stochastic measurement and process noise in the system. The main objective of such observers is to design (possibly globally stable) observers for various classes of nonlinearities using a nonlinear transformation of the original system into a pseudo-linear form or using a dominant linear time invariant (LTI) term in the dynamics (i.e., $\dot{x} = Ax + g(x)$). A nonlinear observer is designed in a recent work [14] for deterministic systems with a special class of nonlinearities that satisfy incremental quadratic inequalities. In [15], a state estimation algorithm for stochastic nonlinear systems is presented for the nonlinearities satisfying the integral quadratic constraint (IQC). In [16], EKF algorithms are developed based on a Carleman approximation (see [17]), which transforms the original nonlinear system into a polynomial form. The dimension of the transformed state space is higher than the original system and increases with the degree of the Carleman approximation. Note that its first degree is equivalent to the Jacobian used in the EKF. In [18], [19], a differential mean-value theorem (DMVT) is used to transform the nonlinearity into a linear parameter varying (LPV) system which leads to an LMI feasibility problem. In [20], a simultaneous input and state estimation method is proposed based on the Gauss-Newton optimization method.

In contrast with the nonlinear transformations used in a deterministic case and the linearization approach used in EKF-like observers, an alternative approach is based on parametrization of nonlinear systems into an “extended linear” form or so called state-dependent coefficient (SDC) form [21], [22]. This paper addresses the problem of observer design in the presence of nonlinearities and stochastic noise by rewriting an Itô stochastic nonlinear system in an SDC form. The SDC parametrization is not unique and there exist multiple choices of such parametrization. An algorithm called “linear matrix inequality state-dependent algebraic Riccati equation” (LMI-SDARE) is proposed which uses the degree of freedom of the SDC form to compute the observer gain. A block diagram describing

formulation that propagates a solution to the differential Riccati equation by integration [36]. The conventional SDARE and SDDRE filters use a single state-dependent parametrization \((A, C)\) to solve the Riccati equation. In contrast, the algorithms presented in this paper use a convex combination of multiple parametrizations to achieve a better estimation performance as shown with the help of numerical simulations in Section VI. If the uniform observability property is satisfied, the SDDRE has a PD solution. In [38], an algorithm is proposed to re-select the parametrization at a particular time-instant if the observability of parametrization is lost.

Notation: Throughout the paper, we adopt the following notation. For a vector \(x \in \mathbb{R}^n\), \(|x|\) denotes the Euclidean norm, \(x_i\) denotes the \(i\)th component of vector \(x\). For a real matrix \(A \in \mathbb{R}^{n \times m}\), \(|A|\) denotes the induced 2-norm; i.e., the maximum singular value of \(A\), \(|A|_F\) denotes the Frobenius norm, \(A_{ij}\) denotes the component in \(i\)th row and \(j\)th column, \((A_{ij})_{a}\) denotes the partial derivative with respect to vector \(a\), \((A_{ij})_{a,a}\) denotes the double partial derivative with respect to components of vector \(a\), \((A_{ij})_{a_1,a_2}\) denotes the partial derivative with respect to \(t\); if \(A\) is square, \(\lambda_{\min}(A)\) and \(\lambda_{\max}(A)\) denote minimum and maximum eigenvalues, and \(\text{tr}(A)\) denotes the trace of \(A\): \(I \in \mathbb{R}^{n \times n}\) denotes the identity matrix; \(\text{Co}\{A_1, \ldots, A_n\}\) denotes the convex hull of matrices \(A_1, \ldots, A_n\); \(E[\cdot]\) denotes the expected value operator, \(E_{y_0}[y(t)]\) denotes the expected value of \(y\) at the time instant \(t\) given the initial value \(y(t_0) = y_0\); and the \(L_2\) norm of a vector is defined in an \(L_2\)-extended space.

II. Preliminaries

A. Brief Review of Contraction Analysis

In this section, contraction analysis [24] for analyzing exponential stability of nonlinear systems is briefly reviewed. Consider a nonlinear, non-autonomous system of the form

\[
\dot{x} = f(x, t)
\]

where \(x(t) \in \mathbb{R}^n\) is a state vector and \(f: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^n\) is a continuously differentiable nonlinear function. With the assumed properties of \((1)\), the exact relation \(\delta \dot{x} = (\partial f(x, t)/\partial x)\delta x\) holds, where \(\delta x\) is an infinitesimal virtual displacement in fixed time. The squared virtual displacement between two trajectories of \((1)\) with a symmetric, uniformly positive definite metric \(M(x, t) \in \mathbb{R}^{n \times n}\) is given by \(\delta x^T M(x, t) \delta x\) (cf. Riemannian metric [39]). Its time derivative is given by

\[
\frac{d}{dt} (\delta x^T M(x, t) \delta x) = \delta x^T \left( \frac{\partial f^T}{\partial x} M(x, t) + \dot{M}(x, t) + M(x, t) \frac{\partial f}{\partial x} \right) \delta x.
\]

(2)

If the following inequality is satisfied

\[
\frac{\partial f^T}{\partial x} M(x, t) + \dot{M}(x, t) + M(x, t) \frac{\partial f}{\partial x} \leq -2\gamma M(x, t) \forall t, \forall x
\]

(3)

for a strictly positive constant \(\gamma\), then the system \((1)\) is said to be contracting with the rate \(\gamma\) and all the system trajectories exponentially converge to a single trajectory irrespective of the initial conditions (hence, globally exponentially stable).

Now consider a perturbed system of \((1)\)

\[
\dot{x} = f(x, t) + d(x, t)
\]

such that the deterministic disturbance \(\|d(x, t)\|\) is bounded. The following lemma shows that the distance between the trajectory of the perturbed system and the trajectory of the globally exponentially stable nominal system remains bounded.

Lemma 1: (Robustness of Contracting Dynamics) [24], [29] Let \(T_1(t)\) be a trajectory of the globally contracting system \((1)\) and \(T_2(t)\) be a trajectory of a perturbed system \((4)\). The smallest distance between \(T_1(t)\) and \(T_2(t)\) is defined by \(S(t) \leq \int_{T_1}^{T_2} ||z|| dt\), where \(z = \Theta(x, t) \delta x\) and \(\Theta^T(x, t) \Theta(x, t) = M(x, t)\) satisfies

\[
S(t) \leq S(t_0) e^{-\gamma(t-t_0)} + \frac{1-e^{-\gamma(t-t_0)}}{\gamma} \sup_{x,t} \|\Theta d\| \ |\forall t \geq t_0.
\]

(5)

As \(t \rightarrow \infty\), \(S(t) \leq \sup_{x,t} ||\Theta d||/\gamma\).

Proof: Differentiating the distance \(S(t)\), we obtain

\[
\dot{S} + \gamma S \leq ||\Theta d||/|24|. \text{ For bounded } ||\Theta d||, \text{ the estimate in } (5) \text{ can be obtained by using the comparison lemma (cf. [40, Lemma 3.4]).}
\]

If the unperturbed system \((1)\) is globally contracting, the perturbed system \((4)\) is finite-gain \(L_2\) stable with \(p \in [1, \infty]\) in the sense of the bounded output function \(y = h(x, d, t)\) with \(\int_{T_1}^{T_2} ||\delta y|| \leq \eta_0 \int_{T_1}^{T_2} ||\delta x|| + \eta_1 ||d||, \forall \eta_0, \eta_1 > 0\) (see [29]) where \(h: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^m\), \(Y_1(t)\) and \(Y_2(t)\) denote the output trajectories of the globally contracting system \((1)\) and its perturbed system \((4)\).

III. Stochastic Contraction Lemma

Consider a stochastically perturbed system of the nominal system \((1)\) represented using an Itô stochastic differential equation

\[
dx = f(x, t) dt + B(x, t) dW, \quad x(0) = x_0
\]

and the conditions for existence and uniqueness of a solution to \((6)\)

\[
\exists L_1 > 0, \forall t, \forall x_1, x_2 \in \mathbb{R}^n:
||f(x_1, t) - f(x_2, t)||_2 + ||B(x_1, t) - B(x_2, t)||_F \leq L_1 ||x_1 - x_2||, \forall L_2 > 0, \forall t, \forall x_1 \in \mathbb{R}^n:
||f(x_1, t)||_2^2 + ||B(x_1, t)||_F^2 \leq L_2 (1 + ||x_1||^2)
\]

(7)

where \(B: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^{n \times d}\) is a matrix-valued function, \(W(t)\) is a \(d\)-dimensional Wiener process, and \(x_0\) is a random variable independent of \(W\) [41].

Consider any two systems with trajectories \(a(t)\) and \(b(t)\) obtained by the same function \(f(\cdot)\) in \((6)\) but driven by independent Wiener processes \(\tilde{W}_1\) and \(\tilde{W}_2\)

\[
dz = \left(\begin{array}{c}
f(a, t) \\
f(b, t)
\end{array}\right) dt + \left(\begin{array}{cc}
B_1(a, t) & 0 \\
0 & B_2(b, t)
\end{array}\right) \begin{pmatrix} d\tilde{W}_1 \\ d\tilde{W}_2 \end{pmatrix}
\]

(8)

where \(z(t) = (a(t)^T, b(t)^T)^T \in \mathbb{R}^{2n}\).
We present the so-called stochastic contraction lemma that uses a state-dependent metric, thereby generalizing the main result presented in [25]. The following lemma analyzes stochastic incremental stability of the two trajectories \( a(t) \) and \( x(t) \) with respect to each other in the presence of noise where the system without noise \( \dot{z} = f(x,t) \) is contracting in a state-dependent metric \( M(x(u,t),t) \), for \( u \in [0,1] \). The trajectories of (6) are parametrized as \( x(0, t) = a \) and \( x(1, t) = b \), and \( B_1(a, t) \) and \( B_2(b, t) \) are defined as \( B(x(0, t), t) = B_1(a, t) \), and \( B(x(1, t), t) = B_2(b, t) \), respectively.

**Assumption 1:** \( \text{tr}(B_1(a, t)^T M(x(a, t), t) B_1(a, t)) \leq C_1, \text{tr}(B_2(b, t)^T M(x(b, t), t) B_2(b, t)) \leq C_2, \overline{m}_x = \sup_{\|x\|} \|M(x(t)x_k)\|, \) and \( \overline{m}_{x^2} = \sup \|\partial^2(M(x(t)))/\partial x^2\|, \) where \( C_1, C_2, \overline{m}_x, \) and \( \overline{m}_{x^2} \) are constants.

**Assumption 2:** The nominal deterministic system (1) is contracting in a metric \( M(x(u,t),t) \) in the sense that (3) is satisfied and \( M(x(u,t),t) \) satisfies the bound \( m \overset{\triangle}{=} \inf_{\|x\|} (\lambda_{\text{min}} M) \). The function \( f \) and the metric \( M \) are the same as in (1) and (3).

**Lemma 2. (Stochastic Contraction Lemma):** Consider the generalized squared length with respect to a Riemannian metric \( M(x(u,t),t) \) defined by \( V(x, \delta x, t) = \int_0^t (\delta x/\partial t)^T M(x(u,t),t)(\delta x/\partial t) d\mu(x,t) \) such that \( m \|\delta x\|^2 \leq V(x, \delta x, t) \). If Assumptions 1 and 2 are satisfied then the trajectories \( a(t) \) and \( b(t) \) of (8), whose initial conditions, given by a probability distribution \( \rho(a_0, b_0) \), are independent of \( dW_1 \) and \( dW_2 \), satisfy the bound

\[
E \left[ \|a(t) - b(t)\|^2 \right] \leq \frac{1}{2} \left( C + E \left[ V(x(0), \delta x(0)) \right] \right) e^{-\gamma t} \tag{9}
\]

where \( \overline{m}_x > 0 \) such that \( \gamma = \gamma - ((\beta_1^2 + \beta_2^2)/2m)(\overline{m}_x + (\overline{m}_{x^2}/2)) > 0 \), \( \gamma \) is the contraction rate defined in (3), \( C = C_1 + C_2 + (\overline{m}_x/\varepsilon) (\beta_1^2 + \beta_2^2) \), \( \beta_1 = \|B_1\|_F \), and \( \beta_2 = \|B_2\|_F \).

**Proof:** By using the Itô formula [3], [41], the stochastic derivative of the Lyapunov function \( V(x, \delta x, t) \) is given by \( dV(x, \delta x, t) = \mathcal{L} V(x, \delta x, t) d\mu + \sum_{i=1}^n \delta x_i V_x(x, \delta x, t) \) \( (B(x,t))^T dW_1 + \overline{m}_x (\delta x, \delta x) \delta B(x(t))^T dW_2 \), where \( \mathcal{L} \) is an infinitesimal differential generator such that

\[
\mathcal{L} V \triangleq \frac{\partial}{\partial t} V_t + \sum_{i=1}^n \left( V_{x_i} f_i + \frac{\partial f}{\partial x} \delta x \right) + \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \left[ V_{x_i x_j} \left( B(x(t))^T(x(t)) \right)_{ij} + V_{\delta x_i \delta x_j} \left( \delta B(x(t)) \delta B^T(x(t)) \right)_{ij} + 2 V_{x_i \delta x_j} \left( B(x(t)) \delta B^T(x(t)) \right) \right]. \tag{10}
\]

Using (6), (10) can be written as

\[
\mathcal{L} V = \int_0^t \left( \frac{\partial}{\partial \mu} \right)^T dM(x(u,t),t) \left( \frac{\partial}{\partial \mu} \right) d\mu + \int_0^t \left( \frac{\partial}{\partial \mu} \right)^T \left( M \left( \frac{\partial f}{\partial x} + \frac{\partial f^T}{\partial x} M \right) \left( \frac{\partial}{\partial \mu} \right) d\mu + V_b \right. \tag{11}
\]

such that \( dM_{ij}(x(u,t),t) = (\partial M_{ij}(x(u,t),t)/\partial t) + (M_{ij}) x \int f(x(u,t),t) \) and

\[
V_b = \int_0^t \sum_{i=1}^n \sum_{j=1}^n M_{ij} \left( \frac{\partial B(x(t))}{\partial \mu} \theta B(x(t))^T \right)_{ij} d\mu + \int_0^t \left[ \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n \sum_{l=1}^n \left( M_{kl}(x(u,t),t) \right)_{x_ix_j} \right.
\]

\[
\left. \left( \frac{\partial}{\partial \mu} \right)^T \left( B(x(t)) B(x(t))^T \right) \right]_{ij} \right) d\mu \tag{12}
\]

where \( x \) is a function of \( \mu \) such that \( x(0, t) = a \) and \( x(1, t) = b \), and \( M_i \) is the \( i \)th row of \( M \). The following bounds can be computed:

\[
\int_0^t \sum_{i=1}^n \sum_{j=1}^n M_{ij} \left( \frac{\partial B(x(t))}{\partial \mu} \theta B(x(t))^T \right)_{ij} d\mu \leq \text{tr} \left( M(a,t) B_1 B_1^T \right) + \text{tr} \left( M(b,t) B_2 B_2^T \right) \tag{13}
\]

\[
\int_0^t \left[ \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \left( M_{i_j}(x(t)) \right)_{x_ix_j} \right. \left. \left( \frac{\partial}{\partial \mu} \right)^T \left( B(x(t)) B(x(t))^T \right) \right]_{ij} d\mu \leq \frac{1}{2} \overline{m}_{x^2} \left( \beta_1^2 + \beta_2^2 \right) \int_0^t \left\| \frac{\partial}{\partial \mu} \right\|^2 d\mu \tag{14}
\]

\[
\int_0^t \left[ \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \left( M_{i_j}(x(t)) \right) \left( \frac{\partial}{\partial \mu} \right)^T \left( B(x(t)) B(x(t))^T \right) \right]_{ij} d\mu \leq 2 \overline{m}_x \left( \beta_1^2 + \beta_2^2 \right) \int_0^t \left\| \frac{\partial}{\partial \mu} \right\|^2 d\mu + \frac{1}{\varepsilon} \tag{15}
\]

where the inequality \( 2a'b' \leq e^{-1}a'^2 + \varepsilon b'^2 \), for scalars \( a' \) and \( b' \) with \( \varepsilon > 0 \), is used. Using (3) and the bounds in (13), (14), and (15), the differential generator in (11) can be bounded above as follows

\[
\mathcal{L} V \leq -2\gamma \int_0^t \left( \frac{\partial}{\partial \mu} \right)^T M(x(u,t),t) \left( \frac{\partial}{\partial \mu} \right) d\mu + \frac{\overline{m}_x}{\varepsilon} \left( \beta_1^2 + \beta_2^2 \right) + \text{tr} \left( M(a,t) B_1 B_1^T \right)
\]

\[
+ \text{tr} \left( M(b,t) B_2 B_2^T \right) \tag{16}
\]
Using the stopping time argument, the integral of the last term in $dV = LV dt + \sum_{i=1}^{m} \sum_{j=1}^{d} V_i(x, \delta x, t)\delta(B(t), t)_{ij} dW_j + V_{\delta x, x}(x, \delta x, t)\delta B(t), t)_{ij} dW_j$ is a martingale (cf. Theorem 4.1 of [42]). Taking the expectation operator on both the sides of $dV$ and using (17) along with Dynkin’s formula (pp. 10 of [3]) yields

$$E_{x_0}[V(x(\mu, t), \delta x(t), t)] - E_{x_0}[V(x(\mu, u), \delta x(u), u)] \leq \int_{u}^{t} (-2\gamma_1 E_{x_0}[V(x(\mu, s), \delta x(s), s)] + C) ds$$

where Fubini’s theorem is used for changing the order of integration [3]. By using the Gronwall-type lemma (see Appendix A), the following inequality can be developed:

$$E_{x_0}[V(x(\mu, t), \delta x(t), t)] \leq \left[ V(x(0), \delta x(0), 0) - \frac{C}{2\gamma_1} \right]^{+} e^{-2\gamma_1 t} + \frac{C}{2\gamma_1}$$

where $[\cdot]^{+} = \max(0, \cdot)$. Integrating (19) with respect to $x_0$, and using $m E[\|a - b\|^2] \leq E[V(x, \delta x, t)] [V(x(0), \delta x(0), 0) - (C/2\gamma_1)]^{+} \leq V(x, \delta x, t)$, $E[V(x(0), \delta x(0), 0)] = \int V(x(0), \delta x(0), 0) dp(x_0)$, the bound on the mean-squared estimation error given in (9) is obtained. Hence, the mean-squared estimation error is exponentially bounded.

### A. Choice of $\varepsilon$ for Optimal Bound in (9)

The contraction rate $\gamma_1$ and the uncertainty bound $C$ in (9) depend on the choice of $\varepsilon$. To derive an optimal choice of $\varepsilon$ so that $C/(2m\gamma_1)$ in (9) is minimized, consider $F(\varepsilon) = C/(2m\gamma_1) = (1/2m)(\gamma - ((\beta_1^2 + \beta_2^2)/2m)(\bar{m}_x + (\bar{m}_x^2/2))) (C_1 + C_2 + (L/\varepsilon))$, where $L = \bar{m}_x (\beta_1^2 + \beta_2^2)$. Computing $dF/\varepsilon = 0$ yields $C_1 + C_2 (\beta_1^2 + \beta_2^2) \bar{m}_x \varepsilon^2 + 2L(\beta_1^2 + \beta_2^2) \bar{m}_x \varepsilon - 2LM\gamma_1 + L(\beta_1^2 + \beta_2^2) (\bar{m}_x^2/2) = 0$, whose solution minimizes the bound $C/(2m\gamma_1)$ in (9).

**Remark 1:** In certain cases, such as the observer design in Section V, the convergence of the trajectories of the solutions of two stochastic systems is difficult to verify by using a state-independent metric, such as $M(t)$ (cf. [43]). Hence, generalization of the stochastic contraction result with a state-dependent metric is important. The bound in (9) reduces to the one obtained in [25] when $M(t)$ or $M$ is constant. It is trivial to verify from (12) that for $M(t)$ or $M$ is constant, the terms related to $(M\xi)_{x}$ and $(M\xi)_{x,x}$ vanish because they are independent of $x$.

### IV. System Formulation for Observer Design

Consider a dynamic system represented by an Itô stochastic differential equation with a measurement equation

$$dx = f(x, t)dt + d(x, t)dt + B(x, t)dW_1(t)$$
$$y = h(x, t) + D(x, t)\nu(t)$$

where $x(t) \in \mathbb{R}^n$ is the state; $y(t) \in \mathbb{R}^m$ is the measurement; $f(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^n$; $h(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^m$; $B(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^{n \times n}$; $D(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^{m \times n}$; $\nu(t)$ is $m$ dimensional white noise formally defined as $dW_2 = \nu(t)dt$; $W_1(t)$ and $W_2(t)$ are standard $n$ and $m$ dimensional independent Wiener processes; and $d(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^n$ is an unknown, bounded, deterministic disturbance. The $d(x, t)$ term is not considered in Theorems 1–2 but is used in Theorem 3 to show the robustness result using $\mathcal{L}_2$ stability.

**Problem Statement:** Given the stochastic system in (20) and the measurement (21), the objective is to design a state observer that estimates the state $x(t)$ using noisy measurements $y(t)$; i.e., given all the noisy measurements up to time $t > 0$, compute $\hat{x}(t)$ such that

$$E\left[\|x(t) - \hat{x}(t)\|^2\right] \leq \zeta_1 E\left[\|x(0) - \hat{x}(0)\|^2\right] e^{-\zeta_2 t} + \epsilon$$

for positive constants $\zeta_1$, $\zeta_2$, and $\epsilon$. The observer is another stochastic differential equation that uses sensor measurements and exponentially forgets the initial conditions to follow the behavior of the original system (20).

The nonlinear system (20) can also be expressed in a state-dependent coefficient (SDC) form

$$dx = A(x, t)xdt + d(x, t)dt + B(x, t)dW_1(t)$$
$$y = C(x, t)x + D(x, t)\nu(t)$$

where $f(x, t) = A(x, t)x$ and $h(x, t) = C(x, t)x$ are parametrized using nonlinear matrix functions $A(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^{n \times n}$ and $C(x, t) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^{m \times n}$. The choice of such parametrization is not unique for $n > 1$. If there exists $A(x, t) \in \text{Co}\{A_1(x, t), A_2(x, t), \ldots, A_s(x, t)\}$ such that

$$f(x, t) = A_1(x, t)x = A_2(x, t)x = \ldots = A_s(x, t)x$$

then there exist an infinite number of parametrizations

$$f(x, t) = A_1(x, t)x = A_2(x, t)x + \ldots + A_{s_i}(x, t)x$$

where $g = \{g_i| i = 1, \ldots, s_1\}$, $g_i \geq 0$ and $\sum_{i=1}^{s_1} g_i = 1$. Similarly, $h(x, t)$ can be parametrized using $C(x, t) \in \text{Co}\{C_1(x, t), C_2(x, t), \ldots, C_{s_2}(x, t)\}$ as

$$h(x, t) = C_1(x, t)x = C_2(x, t)x + \ldots + C_{s_2}(x, t)x$$

where $\eta = \{\eta_i| i = 1, \ldots, s_2\}$, $\eta_i \geq 0$ and $\sum_{i=1}^{s_2} \eta_i = 1$. In the subsequent sections, a convex-optimization problem along with an LMI constraint is presented to optimize a suitable cost metric over the coefficients $g$ and $\eta$.

**Assumption 3:** The convex combination of the matrices $(A_1(x, t), C_1(x, t))$ is selected such that the pair is uniformly observable.

**Remark 2:** Even though the individual parametrization $(A_1(x, t), C_1(x, t))$ is not observable at some points of the state space, the parameters $g$ and $\eta$ can be used to preserve the uniform observability of $(A_1(x, t), C_1(x, t))$. This fact is illustrated using Example 1 below.
Let
\[
\frac{\partial}{\partial x} (A(\varrho, x, t)x) = A(\varrho, x, t) + \Delta_1(\varrho, x, t) \tag{28}
\]
\[
\frac{\partial}{\partial x} (C(\eta, x, t)x) = C(\eta, x, t) + \Delta_2(\eta, x, t) \tag{29}
\]
The matrices \(\Delta_1(\varrho, x, t)\) and \(\Delta_2(\eta, x, t)\) can be evaluated by multiplying the rows of \(A(\varrho, x, t)\) and \(C(\eta, x, t)\) by \(x(t)\) and computing the partial derivatives of the entries of \(A(\varrho, x, t)\) and \(C(\eta, x, t)\) matrices with respect to \(x(t)\).

**Assumption 4:** The Euclidean norm of the state vector \(\|x(t)\|\) is upper bounded by a constant \([36, 44, 45]\); i.e., \(x(t) \in D\) where \(D \subset \mathbb{R}^n\) is a compact domain. The SDC parametrization \(A(\varrho, x, t)\) and \(C(\eta, x, t)\) is such that the following inequalities hold \([44]\):

\[
\|\Delta_1(\varrho, x, t)\| \leq \delta_1, \quad \|\Delta_2(\eta, x, t)\| \leq \delta_2, \quad \delta_3 \leq \|C(\eta, x, t)\| \leq \delta_3 \tag{30}
\]

where \(\delta_1, \delta_2, \delta_3\) and \(\delta_3\) are positive scalars.

**Remark 3:** Assumption 4 is satisfied by many engineering applications, e.g., pose estimation of a robot moving on earth’s surface, state estimation for aircraft guidance and control, etc. Assumption 4 does not imply any assumption on the stability of the system \((20)\) or the incremental stability of the observer design. It is only assumed that the trajectories of the original system remain bounded within an arbitrarily large compact set.

**Example 1:** We illustrate how the parameters \(\varrho, \eta\) can be used to minimize the uncertainty in the SDC parametrization and avoid loss of observability of the pair \((A, C)\). Consider a nonlinear function \(f(x) = (x_1x_2, -x_2)^T\), where \(x = (x_1, x_2)^T \in D \subset \mathbb{R}^2\), and an observation matrix \(C = (1, 0)\).

Let two parametrizations be selected as \(A_1 = \begin{pmatrix} 0 & x_1 \\ 0 & -1 \end{pmatrix}\), \(A_2 = \begin{pmatrix} x_2/2 & x_1/2 \\ 0 & -1 \end{pmatrix}\). Consider a convex combination \(f(x) = \varrho_1 A_1 x + \varrho_2 A_2 x\) such that \(\varrho_1 + \varrho_2 = 1\). The corresponding matrix \(\Delta_1(\varrho, x)\) is \(\Delta_1 = \begin{pmatrix} \varrho_2 x_2/2 + \varrho_1 x_2 & \varrho_2 (x_1/2) \\ 0 & 0 \end{pmatrix}\), whose Frobenius norm is bounded inside the compact domain \(D\). The parameters \(\varrho\) can be used to preserve the observability of the pair \((\varrho_1 A_1 + \varrho_2 A_2, C)\). The pair \((\varrho_1 A_1 + \varrho_2 A_2, C)\) is unobservable if \(\varrho_1 x_1 + (\varrho_2 x_2/2) = 0\). To avoid the loss of observability, a nonzero \(\varrho_1\) is selected for \(x_1 = 0\), a nonzero \(\varrho_2\) is selected for \(x_1 = 0\), and \(\varrho_1, \varrho_2\) are selected such that \(\varrho_1 x_1 + (\varrho_2 x_2/2) \neq 0\). To avoid loss of observability, a nonzero \(\varrho_1\) is selected for \(x_1 = 0\), a nonzero \(\varrho_2\) is selected for \(x_1 = 0\), and \(\varrho_1, \varrho_2\) are selected such that \(\varrho_1 x_1 + (\varrho_2 x_2/2) \neq 0\). Note that the pairs \((A_1, C)\) and \((A_2, C)\) are not observable for \(x_1 = 0\), and \(x_2 = 0\), respectively. The problem of loss of observability of an individual pair can be avoided by suitably choosing the coefficients \(\varrho\). In Section V-B, a linear matrix inequality (LMI) is formulated which includes constraints on \(\varrho\) and \(\eta\) to avoid loss of observability of the pair \((A, C)\).

**V. Observer Design and Stability Analysis**

In this section, an observer is designed for the stochastic system in \((20)\) and \((23)\) to estimate the state \(x(t)\). The estimate is denoted by \(\hat{x}(t) \in \mathbb{R}^n\). A stochastic observer for the system in \((23)\) is designed as

\[
d\hat{x} = A(\varrho, \hat{x}, t)\hat{x}dt + K(\hat{x}, t)(y - C(\eta, \hat{x}, t)\hat{x}) dt \tag{31}
\]

which can be written in the following form using \((24)\):

\[
d\hat{x} = [A(\varrho, \hat{x}, t)\hat{x} + K(\hat{x}, t)(C(\eta, x, t)\hat{x} - C(\eta, \hat{x}, t)\hat{x})] dt + K(\hat{x}, t)D(x,t)dW_2 \tag{32}
\]

where \(dW_2\) is defined below \((21)\). The observer gain \(K(\hat{x}, t)\) is given by

\[
K(\hat{x}, t) = P(\hat{x}, t)C^T(\eta, \hat{x}, t)R^{-1}(\hat{x}, t) \tag{33}
\]

where \(R(\hat{x}, t) = D(\hat{x}, t)D^T(\hat{x}, t)\) is a positive definite approximation of the measurement noise covariance matrix and the positive definite (PD) symmetric matrix \(P(\hat{x}, t)\) is a solution to

\[
dP(\hat{x}, t) = (A(\varrho, \hat{x}, t)P(\hat{x}, t) + P(\hat{x}, t)A^T(\varrho, \hat{x}, t) + 2\alpha P(\hat{x}, t) - P(\hat{x}, t)) \times (-2\kappa I + C^T(\eta, \hat{x}, t)R^{-1}(\hat{x}, t)C(\eta, \hat{x}, t)) \times P(\hat{x}, t) dt \tag{34}
\]

where \(\alpha > 0\) and \(\kappa > 0\). The matrices \(A(\varrho, \hat{x}, t)\) and \(C(\eta, \hat{x}, t)\) are obtained via SDC parametrizations in \((26)\) and \((27)\). Equation \((34)\) can be integrated with a positive definite symmetric initial condition \(P(0) > 0\).

If the matrices \(A(\varrho, \hat{x}, t)\) and \(C(\eta, \hat{x}, t)\) are not state-dependent, then the exact solution of the differential Riccati equation can be derived, which gives an optimal gain of the Kalman-Bucy filter with \(\kappa = 0\).

**Assumption 5:** There exist two time-varying scalar functions \(p_u(t)\) and \(p_t(t)\) such that the positive definite solution \(P(\hat{x}, t)\) of the differential Riccati \((34)\) satisfies the bound

\[
p_t(t)I \leq P^{-1}(\hat{x}, t) \leq p_u(t)I, \quad \forall t \geq 0. \tag{35}
\]

The time-varying bounds in \((35)\) can be replaced by constants using \(\bar{p} = \sup_t p_u(t)\) and \(\underline{p} = \inf_t p_t(t)\).

**Remark 4:** If the pair \((A(\varrho, x, t), C(\eta, x, t))\) is uniformly observable by Assumption 3, the solution to \((34)\) satisfies the bounds in \((35)\) (cf. \([6, 43, 46, \text{Theorem 7}], [47, \text{Lemma 2}]\)).

**A. Observer Stability by Contraction Analysis**

In this section, stochastic incremental stability of the observer is studied using the results of Lemma 2. The analysis is performed in two steps. First, global exponential convergence (contraction) of noise-free trajectories of the observer in \((31)\) towards noise-free trajectories of the original system \((20)\) is proved in Theorem 1 using partial contraction theory \([48]\). Second, the bound on the mean-squared distance between the trajectories of the original system with process noise and the trajectories of the observer with measurement noise is computed in Theorem 2.

Notice that noise-free and disturbance-free trajectories of the systems \((23)\) and \((31)\) can be represented by the following
virtual system of $q \in \mathbb{R}^n$:

$$
\dot{q} = f_0(q, \mu(t)) dt + B_q(\mu(t), t) dW
$$

(37)

For $q = x$, (36) reduces to a noise-free and disturbance-free version of (20) and for $q = \hat{x}$, (36) yields noise-free version of (31). Hence, $q = x$ and $q = \hat{x}$ are particular solutions of the virtual system (36). Consider a stochastic system

$$
\dot{q} = f_0(\mu(t), t) dt + B_q(\mu(t), t) dW
$$

(38)

Proof: We show that the virtual auxiliary system (36) is contracting. Note again that $\hat{x}(t)$ of (31) without noise and $x(t)$ of (20) without noise and disturbance are particular solutions of (36). Using (28) and (29), the virtual dynamics of (36) can be expressed as

$$
\dot{q} = (A(\eta, q, \hat{x}) - K(\hat{x}, t)C(\eta, q, t)) q + \phi(\eta, q, \hat{x}, t) \delta q
$$

(39)

where $\phi(\eta, q, \hat{x}, t) = \Delta_1(q, t) - K(\hat{x}, t)\Delta_2(q, t)$. In the virtual dynamics (39), the term $\phi(\eta, q, \hat{x}, t)$ can be seen as an uncertainty term, which is bounded due to Assumptions 3–5. To analyze the contraction of the infinitesimal virtual displacement vector $\delta q$, consider the rate of change of the squared length in the metric $P^{-1}(q, t)$

$$
\frac{d}{dt} (\delta q^T P^{-1}(q, t) \delta q)
$$

(40)

where $P^{-1} = -P^{-1} \dot{P}^{-1}$, and $-K(\hat{x}, t)R(q, t)K^T(\hat{x}, t) - K(q, t)R(q, t)K^T(q, t)$ is added and subtracted. Using the bounds $\mathbb{I} \geq R \geq I$, and $-P^{-1}(q, t)K(\hat{x}, t)R(q, t)K^T(\hat{x}, t) \leq -(p^2/\delta^2 + \bar{p}^2/\bar{\delta}^2) I = -2\kappa_2 I$, and substituting (33), and (38), (40) can be expressed as

$$
\frac{d}{dt} (\delta q^T P^{-1}(q, t) \delta q) \leq \delta q^T \left(-2\alpha P^{-1}(q, t) - 2\kappa I - 2\kappa_2 I\right) \delta q + P^{-1}(q, t) \phi + \phi^T P^{-1}(q, t) \delta q
$$

(41)

As stated previously, $\phi(\eta, q, \hat{x}, t)$ is norm-bounded according to Assumptions 3–5. The following bound can be established using Assumptions 4 and 5:

$$
\|P^{-1}(q, t) \phi + \phi^T P^{-1}(q, t) \delta q\| \leq 2\kappa_1
$$

(42)

where $\kappa_1 = \bar{p} \delta_1 + (\bar{p}/\bar{\delta}) \delta_2 \delta_2$. Using (42), for sufficiently large $\alpha$ and $\kappa$, (41) satisfies

$$
\frac{d}{dt} (\delta q^T P^{-1}(q, t) \delta q) \leq -2\alpha \delta q^T P^{-1}(q, t) \delta q
$$

(43)

where $\alpha > \alpha_1 > 0$, and

$$
\kappa_1 - \kappa_2 \leq \kappa + (\alpha - \alpha_1) \bar{p}
$$

(44)

Using (43), the bound on the squared length can be established

$$
\delta q^T P^{-1}(q, t) \delta q \leq \delta q^T (0) P^{-1}(q(0), 0) \delta q(0) e^{-2\alpha_1 t}
$$

(45)

which reduces to

$$
\|\delta q(t)\| \leq \sqrt{\frac{\|\delta q(0)\|}{\bar{p}}} e^{-\alpha_1 t}.
$$

(46)

Using the equivalence of the norm of the distance between $x$ and $\hat{x}$, $\|x - \hat{x}\| = \|f_0(x, t, \mu(t))\| \leq \|f_0(0)\| = \|\delta q(0, \mu(t))\| = \|\delta q(0)\| e^{-\alpha_1 t}.$

Remark 5: Note that (38) is evaluated at an auxiliary variable $q$. For the observer implementation, (34) is used. Theorem 1 shows that any trajectory of $q$ converges; i.e., trajectories of $q$ and $\hat{x}(t)$ converge to each other and hence the noise-free solution of (34) converges towards the solution of (38).

Remark 6: If the Jacobian of the nonlinear function $h(x, t)$ is used instead of the SDC parametrization, the bound $\kappa_1$ becomes smaller because $\Delta_2(q, t) = 0$.

Assumption 6: Let $\bar{p}_x = \sup_{t > 0, \mu(t), q} \|P^{-1}_{ij}\|$, $\bar{p}_x^2 = \sup_{t > 0, \mu(t), q} \|\partial^2 (P^{-1})/\partial q_i \partial q_j\|$, $\|B(x, t)\|$. The state estimates can be bounded within the compact domain using tools, such as saturation or projection algorithms (cf. [13], [49], [50]).

Theorem 2: (Stochastic Stability) If Assumptions 3–6 are satisfied, the mean-squared estimation error of the observer in (31) is exponentially bounded with the bound

$$
E\left[\|x - \hat{x}\|^2\right] \leq \frac{1}{\bar{p}} \left(E\left[V(q(0), \delta q(0), 0)\right] e^{-2\alpha_1 t} + \frac{\delta_1}{\alpha_1} \right)
$$

(47)
where
\[
\delta_4 \geq \frac{\bar{p}_x}{\varepsilon_1} \left( \bar{b}_r^2 + \frac{\delta_1^2}{\varepsilon_2^2} \text{tr} (P^2 (\hat{x}, t)) \right) + \delta_2 + \frac{\delta_1^2}{\varepsilon_2^2} \text{tr} (P (\hat{x}, t))
\] (48)
where \( \alpha_3 \triangleq \alpha_1 - (\kappa_p/2p)(\varepsilon_1 \bar{p}_x + (\bar{p}_x/2)) \) such that \( \alpha_1 > (\kappa_p/2p)(\varepsilon_1 \bar{p}_x + (\bar{p}_x/2)), \varepsilon_1 > 0, \alpha_1 > 0 \) is defined in (43) and \( \kappa_p = \bar{b}_r^2 + \frac{\delta_1^2}{\varepsilon_2^2} \text{tr} (P^2 (\hat{x}, t)). \)

Proof: We prove this theorem as a special case of Lemma 2. To prove that the mean-squared estimation error \( E[||x - \hat{x}||^2] \) is exponentially bounded, consider a Lyapunov-like function defined by \( V(q, \delta q, t) = \int_0^1 (|\partial q/\partial \mu|^2 + |\partial q/\partial \mu|) d\mu \), where \( q(\mu = 0) = x \) and \( q(\mu = 1) = \hat{x} \). For conciseness of the presentation, we only compute the differential generator of \( V(q, \delta q, t) \) by following the development in the proof of Lemma 2 for the system in (37)

\[
\mathcal{L} V(q, \delta q, t) = \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T \left( \frac{d}{dt} P^{-1}(q, \mu, t) \right) \frac{\partial q}{\partial \mu} d\mu + \int_0^1 \left( \frac{\partial \eta v}{\partial q} \right)^T \left( \frac{d}{dt} P^{-1}(q, \mu, t) \right) \frac{\partial \eta v}{\partial q} d\mu + V_2
\] (49)

where \( \eta v \) is defined in (36), note that \( q = q(\mu, t) \) with \( q(0, t) = x \) and \( q(1, t) = \hat{x} \), computation of \( V_2 \) is shown in Appendix B, and the upper bound of \( V_2 \) is given by

\[
V_2 = \text{tr} \left( B(x, t)^T P^{-1}(x, t) B(x, t) \right) + (K(\hat{x}, t) D(x, t))^T P^{-1}(\hat{x}, t) K(\hat{x}, t) D(x, t)
\]

\[
+ \bar{p}_x \left( \bar{b}_r^2 + \frac{\delta_1^2}{\varepsilon_2^2} \text{tr} (P^2 (\hat{x}, t)) \right)
\]

\[
\times \left( \int_0^1 \left| \frac{\partial q}{\partial \mu} \right|^2 d\mu + \int_0^1 \| \frac{\partial \eta v}{\partial q} \|^2 d\mu \right)
\]

\[
+ \frac{1}{2} \bar{p}_x \left( \bar{b}_r^2 + \frac{\delta_1^2}{\varepsilon_2^2} \text{tr} (P^2 (\hat{x}, t)) \right) \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 d\mu.
\]

The derivative of \( \eta v \) with respect to \( q \) is given by

\[
\frac{\partial \eta v}{\partial q} = A(q, q, t) - P(\hat{x}, t) C^T (\eta, \hat{x}, t) R^{-1}(\hat{x}, t)
\]

\[
\times C(\eta, q, t) + \phi(q, \eta, q, t).
\]

Substituting (51) into (49), and using \(-P^{-1}(q, \mu) K(\hat{x}, t) R(q, \mu) K^T (\hat{x}, t) P^{-1}(q, \mu) \leq -2\kappa_2 I\) yields

\[
\mathcal{L} V \leq \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T \left( \frac{d}{dt} P^{-1}(q, \mu, t) \right) \frac{\partial q}{\partial \mu} d\mu + \int_0^1 \left( \frac{\partial \eta v}{\partial q} \right)^T \left( \frac{d}{dt} P^{-1}(q, \mu, t) \right) \frac{\partial \eta v}{\partial q} d\mu
\]

\[
\times \left[ A(q, q, t) P(q, t) + P(q, t) A^T (q, q, t) - P(q, t) C(\eta, q, t) R^{-1}(q, \mu) K(\hat{x}, t) \right.
\]

\[
+ (K(\hat{x}, t) - K(q, t)) R(q, \mu) (K(\hat{x}, t) - K(q, t))^T
\]

\[
- 2\kappa_2 I + \phi P(q, t) + P(q, t) \phi^T \]

\[
\times P^{-1}(q, t) \left( \frac{\partial q}{\partial \mu} \right) d\mu + V_2.
\]

Using (42), \((d/dt) P^{-1} = -P^{-1} ((d/dt) P) P^{-1}\), and the Riccati (38), and the results of Theorem 1, the differential generator satisfies the following inequality:

\[
\mathcal{L} V \leq -2\alpha_1 \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T P^{-1}(q, t) \left( \frac{\partial q}{\partial \mu} \right) d\mu + \bar{V}_2
\]

\[
= -2\alpha_1 V(q, t) + \bar{V}_2
\] (53)

where \( \alpha_1 \) is defined below (43). Using Assumption 6, and derivations in (11)–(16), the following upper bound is obtained:

\[
\mathcal{L} V(q, \delta q, t) \leq -2\alpha_3 V(q, \delta q, t) + \delta_4
\] (54)

where \( \delta_4 \) is defined in (48), and \( \alpha_3 \) is defined below (48). The properties of trace operator: \( \text{tr}(XY) \leq \text{tr}(X) \text{tr}(Y) \), \( \text{tr}(XY) \leq \|Y\| \text{tr}(X) \), and \( \sqrt{\text{tr}(Y^T Y)} = \|Y\| \) for positive semi-definite matrices \( X \) and \( Y \), and \( \text{tr}((K(\hat{x}, t) D(x, t))^T P^{-1}(\hat{x}, t) K(\hat{x}, t) D(x, t)) \leq \delta_1^2 / \varepsilon_2^2 \text{tr} (P (\hat{x}, t)) \) are used to derive the \( \delta_4 \) bound. Using the development in the proof of Lemma 2, the bound in (47) is obtained.

Remark 8: In general, the process and measurement noise terms do not vanish. Hence, the constant \( \delta_4 \), which is a function of the process and measurement noise intensities, will not be zero. This implies that \( \mathcal{L} V(q(\mu, t), \delta q(\mu, t)) \) may not always be non-positive and \( V(q(\mu, t), \delta q(\mu, t)) \) may sometimes be increasing. Thus, \( E[V(q(\mu, t), \delta q(\mu, t))] \leq V(q(\mu, s), \delta q(s, s) \forall 0 < s < t < \infty \) may not always be true; i.e., \( V(q(\mu, t), \delta q(t, t)) \) may not be a supermartingale. The supermartingale inequality [3], [41] cannot be used to prove stability in an almost-sure sense [25].

Remark 9: Theorems 1–2 can be used to analyze stability of extended Kalman filter (EKF) using \( \kappa = 0, \alpha = 0 \) in (34).

The observer (31)–(34) is shown to be robust against the disturbances and noise in the sense of finite expected value of the \( L_2 \) norm of the estimation error with respect to the disturbances and noise acting on the system. The \( L_2 \) norm bound is derived for the estimation error of a generalized state \( g(t) = E(t)x(t), \) where \( L(t) \in \mathbb{R}^{m \times n} \) satisfies \( LT(t)L(t) \geq \ell I, \) where \( \ell \) is a positive constant.

Corollary 1: (\( L_2 \) robustness) If Assumptions 3–6 are satisfied, the observer in (31)–(34) is robust against the external disturbances and satisfies the following \( L_2 \) norm bound on the estimation error:

\[
E_{q_0} \left[ \int_0^1 \| g(\tau) - \hat{g}(\tau) \|^2 d\tau \right] \leq \bar{\ell} \| x(0) - \hat{x}(0) \|^2_{P^{-1}(0)} + \bar{\ell} E_{q_0} \left[ \int_0^1 \left( \xi_2^2 \| d(x, \tau) \|^2 \right) d\tau \right]
\] (55)

where \( \delta_4 \) is defined in (48), \( \| \cdot \|^2_{P^{-1}(0)} \) is the Euclidean vector norm square with respect to weight \( P^{-1}(0), \xi_1 = (1 - \theta)2\alpha_3 \bar{p}_x, \xi_2 = \bar{p}_x / \bar{p} > 2, \bar{p}_x > 0, \alpha_3 = q(\mu = 0, t = 0), \) and \( 0 < \theta = (\varepsilon_2 \bar{p}_x)/(2\alpha_3 \bar{p}_x) < 1. \)

Proof: See Appendix C.
B. Computation of \( P \) and LMI Formulation

To compute the estimator gain, a PD solution \( P(\hat{x}, t) \) of (34) is required. In this section, algorithms are presented to compute the matrix \( P(\hat{x}, t) \).

1) Main Algorithm (LMI-SDARE): In this section, the optimal observer gain design algorithm, called the linear matrix inequality state-dependent algebraic Riccati equation (LMI-SDARE), is presented. In the LMI-SDARE algorithm, \( P(\hat{x}, t) \) is approximated to its steady state value; i.e., zero \([51]\). The differential Riccati (34) can be converted into the following algebraic Riccati inequality (cf. \([23, pp. 114–115]\))

\[
A(\varrho, \hat{x}, t)P + PA^T(\varrho, \hat{x}, t) + 2\alpha P - PC^T(\varrho, \hat{x}, t) \times R^{-1}(\hat{x}, t)C(\varrho, \hat{x}, t)P + 2\kappa PP \leq 0.
\]  

(56)

Proposition 1: The inequality (56) can be converted to the following linear matrix inequality (LMI) by Shor’s relaxation \([52]\) in terms of variables \( Q = P^{-1} \), \( Q_{\varrho} = \varrho_i Q \), \( \varrho_i \), \( \forall i = \{1, \ldots, s_1\} \), \( \eta_i \), \( \forall i = \{1, \ldots, s_2\} \), and \( \eta_{ij} \).

\[
\sum_{i=1}^{s_1} Q_{\varrho_i} A_i(\hat{x}, t) + \sum_{i=1}^{s_1} A_i^T(\hat{x}, t)Q_{\varrho_i} + 2\alpha Q - \Upsilon I + \frac{1}{2\kappa}I \leq 0.
\]  

(57)

where \( \Upsilon = \sum_{i,j=1}^{s_2} \eta_{ij} C_i^T(\hat{x}, t)R^{-1}(\hat{x}, t)C_j(\hat{x}, t) \), and

\[
Q > 0, \quad \sum_{i=1}^{s_1} Q_{\varrho_i} A_i(\hat{x}, t) \hat{x} = Qf(\hat{x}),
\]  

(58)

\[
\text{sym} \left[ \begin{array}{cc} I & Q \\ \varrho_i I & Q_{\varrho_i} \end{array} \right] \geq 0, \quad \sum_{i=1}^{s_1} \varrho_i = 1, \quad \varrho_i \in [0, 1],
\]  

(59)

\[
\sum_{i=1}^{s_2} \eta_i = 1, \quad \eta_j \in [0, 1], \quad oc_k(\varrho, \eta, \hat{x}) < 0, \quad \forall k = 1, \ldots, n_o
\]  

(60)

\[
W_i = \begin{bmatrix} 1 & \eta_i \\ \eta_{i_0} \end{bmatrix} \geq 0, \quad \eta_{i,j} \in [0, 1]
\]  

(61)

\[
\sum_{i=1}^{s_2} \eta_{i,j} + \sum_{j=1, j \neq i}^{s_2} \eta_{i,j} = 1
\]  

(62)

where \( \text{sym}(\cdot) \) is a symmetric part of a matrix, \( oc_j(\varrho, \eta, \hat{x}) < 0, \quad \forall j = 1, \ldots, n_o \) denotes \( n_o \) number of convex constraints to maintain the observability of the pair \((A, C)\). Note that \( oc_j(\varrho, \eta, \hat{x}) < 0 \) might impose \( \varrho_j \geq \chi_j > 0 \) and \( \eta_j \geq \psi_j > 0 \) for some \( js \), where \( \chi_j \) and \( \psi_j \) are small constants.

Proof: First multiplying (56) by \( Q = P^{-1} \) from left and right side yields

\[
QA(\varrho, \hat{x}, t) + A^T(\varrho, \hat{x}, t)Q + 2\alpha Q - C^T(\varrho, \hat{x}, t) \times R^{-1}(\hat{x}, t)C(\varrho, \hat{x}, t)P + 2\kappa I \leq 0.
\]  

(63)

By applying the Schur complement lemma to (56), we obtain the bilinear matrix inequality (BMI) \([52, 53]\)

\[
\begin{bmatrix} \sum_{i=1}^{s_1} Q_{\varrho_i} A_i(\hat{x}, t) + \sum_{i=1}^{s_1} A_i^T(\hat{x}, t)Q_{\varrho_i} + 2\alpha Q - \Upsilon_1 I \\ I \end{bmatrix} \leq 0
\]  

(64)

with the constraints in (58) where \( \Upsilon_1 \) is given by

\[
\Upsilon_1 = \sum_{i,j=1}^{s_2} \eta_{ij} C_i^T(\hat{x}, t)R^{-1}(\hat{x}, t)C_j(\hat{x}, t).
\]  

(65)

The multiplication of components of \( \eta \) in \( \Upsilon_1 \) makes (64) a BMI. To convert the BMI to an LMI, new lifting variables \( \eta_{i,j} \) are defined. Using the lifting variables and the Shor’s relaxation \([52]\), the BMI in (64) is converted into an LMI in terms of the variables \( Q, Q_{\varrho_i}, \eta_i, \) and \( \eta_{i,j} \), by writing \( \Upsilon_1 \) as

\[
\Upsilon_1 = \sum_{i,j=1}^{s_2} \eta_{ij} C_i^T(\hat{x}, t)R^{-1}(\hat{x}, t)C_j(\hat{x}, t)
\]  

with the constraints (61)-(62). The Shor’s relaxation is applied for each individual constraint \( \eta_i, \eta_i \eta_j \), \( \forall i \in \{1, \ldots, s_2\} \). Note that due to Shor’s relaxation the rank 1 constraints on \( W_i \)s are ignored. For deriving the constraints on the cross terms \( \eta_{i,j} \), the equality \( \sum_{i=1}^{s_2} \eta_i^2 = 1 \) is used, which can be written as (62) in terms of \( \eta_{i,j} \) by using \( \eta_i \eta_j = \eta_{i,j} \). A similar constraint is recently derived in \([54]\). To take care of the \( \varrho_i Q = Q_{\varrho_i} \), constraint, new constraints on \( Q \) and \( Q_{\varrho_i} \) are given in (59).

Additional constraints in the form \( oc_k(\varrho, \eta, \hat{x}) < 0 < \) can be formulated so that the pair \((A, C)\) is observable. These constraints can be obtained by symbolically computing the observability matrix and formulating state-dependent constraints for which the observability matrix is full rank. The observability constraints make sure that Assumption 3 is satisfied. See Example 1 for an example of the observability constraint. If the observability constraints are not convex, relaxation methods can be used to approximate the observability constraints to convex constraints \([55]\). The formulation in (57), (58) is useful for implementation purposes when there are multiple \( A_i(\hat{x}, t) \).

If the observability constraint \( oc_k(\cdot) \) is an affine function of \( \varrho \) only then those terms can be added as \( \sum_{i=1}^{s_1} oc_k(\varrho) \varrho_i Q < 0 \), which is equivalent to \( \sum_{i=1}^{s_1} oc_k(\varrho) \varrho_i < 0 \). If \( oc_k(\cdot) \) is an affine function of \( \eta \) only then those terms can be added as \( \sum_{j=1}^{s_2} oc_k(\eta) \eta_i < 0 \). The solution to the LMI can be used to minimize the mean-squared bound \( \delta_1/2p_{O3} \). Towards this goal, three conditions are derived and briefly explained. First, based on (48), minimizing \( tr(P^2(\hat{x})) \) minimizes \( \delta_1 \) and \( 1/2p_{O3} = 1/(2\alpha_{11} - \kappa \rho_i(\varepsilon_{1p} + (p_{x_2}/2))) \), and minimizing \( tr(P(\hat{x})) \) minimizes \( \delta_4 \). The function \( tr(P^2(\hat{x})) \) is not a convex function of \( P(\hat{x}) \), but we can minimize a convex upper bound \( tr(P(\hat{x})^2) \). Second, the constraint (44) should be satisfied for deterministic constricted. For given \( \alpha, \kappa_1, \) and \( \kappa_2 \) maximizing \( \kappa + \alpha \lambda_{\min}(Q) \) maximizes \( \alpha_1 \lambda_{\min}(Q), \) which minimizes \( 1/(2\alpha_{11} - \kappa \rho_i(\varepsilon_{1p} + (p_{x_2}/2))) \). Third, minimizing \( \lambda_{\max}(Q) \) reduces \( \delta_4 \). A convex objective function summarizing all three conditions can be formulated in terms of \( Q \) and \( \kappa \) as

\[
\min \left( \Lambda_1 tr(Q^{-1})^2 - \Lambda_2 \kappa - \Lambda_3 \alpha \lambda_{\min}(Q) + \Lambda_4 \lambda_{\max}(Q) \right)
\]  

subject to (57)-(62)

(66)

where \( \Lambda_1, \Lambda_2, \Lambda_3 \) and \( \Lambda_4 \) are the normalized weight parameters selected by the user. The decision variables for the optimization are \( Q, Q_{\varrho_i}, \eta_i, \eta_{i,j}, \) and \( \kappa \). The variable \( \alpha \) is usually selected by the user.

1This cost function is one of many choices a user can select.
In addition to the constraints in (66), an inequality constraint (44) can be included in the LMI formulation as\footnote{constraint (44) can be included in the LMI formulation as $\kappa_1 - \kappa_2 \leq \kappa + \alpha \lambda_{\text{min}}(Q) - \alpha_2$ where $\alpha$ and $\kappa_1$ are selected by the user. To make (44) a linear constraint, a new variable $\alpha_2 = \alpha_1 \lambda_{\text{min}}(Q) > 0$ is formed with $(\alpha - \alpha_1) \lambda_{\text{min}}(Q) = \alpha \lambda_{\text{min}}(Q) - \alpha_2 > 0$. The constraint makes sure that the condition (44) is satisfied by the estimator gain.}

The LMI contains state-dependent matrices which can be solved at each time instant using the polynomial-time interior point methods [56]. The solution of the LMI optimization problem (66) returns the optimal feasible values of the decision variables to improve the convergence rate or to reduce the mean-squared estimation error with respect to the external disturbances acting on the system. The solution to the LMI problem provides a suboptimal criterion to select the estimator gain.

2) Variations of LMI-SDARE:

In this section, two variations of the LMI-SDARE algorithm are presented, which may be computationally less expensive during real-time computation than the LMI-SDARE algorithm at the cost of reduced performance in terms of the mean-squared estimation error.

1) CSDRE Algorithm: The differential Riccati equation (34), which uses the convex combination of multiple SDC forms of $A$ and $C$, can be integrated with some PD initial condition $P(\dot{x}(0), 0)$ to compute $P(\dot{x}, t)$ matrix at each filter update step. An alternate approach is to solve (56) with equality, which forms an ARE. It is shown in practice that a solution to a state-dependent ARE is formed with

\[
Q(x, \dot{x}, t) = \begin{bmatrix}
0 & x^T \\
-x & 0
\end{bmatrix}
\]

Formulas of $A$ and $C$ are given by $A_i(\dot{x})$, $C_i(x)$, where $A_i(\dot{x})$ and $C_i(x)$ are vertices of the convex hulls. The convex hull of $A$ and $C$ are computed using the upper and lower bounds of the individual entries inside the domain $D$. The difference between CSDRE and Fixed-SDARE algorithms is that the CSDRE algorithm uses fixed $\rho$ and $\eta$ whereas the Fixed-SDARE algorithm uses fixed $(A, C)$, and $\rho$ and $\eta$ are computed using a list of LMIs. A similar approach for the Lipschitz nonlinear systems is developed in [18] by assuming that the Jacobian of the nonlinear function belongs to a convex polytope. The LMI in (66) can be solved for each vertex of the polytope. The observer gain can be computed using the common feasible solution $Q$ to the LMIs (57)-(62). The convergence of the estimator can be easily shown with the results of Theorem 1 (cf. Section 4.3 of [53]). Although the Fixed-SDARE algorithm permits offline computation of the gains, a new vertex of the convex hull adds another LMI constraint to the feasibility problem (66). Moreover, the convex hull may use conservative bounds of the parametrization [53].

Remark 10: For a standard differential inclusion (DI) method (cf. [23, p. 62]) where a common solution $Q$ is computed that satisfies multiple LMI inequalities formed using $A_i$ and $C_i$, a common solution $Q$ may not exist if one of the parameterizations $(A_i, C_i)$ is not observable. Similar to the Fixed-SDARE algorithm, a standard DI approach is very conservative since it has to satisfy all the LMIs. In a standard DI method, observability constraints cannot be exploited as can be done in the proposed LMI-SDARE method.

VI. Numerical Simulations

In this section, the performance of the observer (31)-(34) along with (66) is evaluated using two examples.

A. 2D Robot Pose and Landmark Position Estimation Example

In this example, the filter estimates the robot position and orientation, and 2D landmark positions in the world frame $W$ using the landmark positions measured in the robot body frame $B$. Let $r(t) \in \mathbb{R}^2$ be robot’s position, $\theta(t) \in [0, 2\pi)$ be robot’s orientation in $W$, $v(t) \in \mathbb{R}$ denote linear velocity of the robot in the world frame, and $\omega(t) \in \mathbb{R}$ denote the body angular velocity of the robot. Let the state vector be defined by $x = (x^T(t), \theta(t))^T$, where $x_i(t) = \theta(t)$. The positions for $n_l$ landmarks in the world frame are $x_i(t) = (l_i^T(t), \ldots, l_i^T(t), l_i^T(t))$, where $l_i \in \mathbb{R}^2$, $\forall i = \{1, 2, \ldots, n_l\}$ is the position of $i$th landmark in $W$. The state dynamics are given by $\dot{x}_v = (v \cos(\theta), v \sin(\theta), \omega)^T$, $\dot{l}_i = 0$, $\forall i = \{1, 2, \ldots, n_l\}$ with the measurement model $y_i = R^T(\theta)(r - l_i)$, $\forall i = \{1, 2, \ldots, n_l\}$, where $y_i(t) \in \mathbb{R}^2$ denotes the measurement of each landmark in the robot’s coordinate frame, and $R(\theta)$ is a rotation matrix. The robot motion parameters are selected as $v = 1 \text{ m/s}$, $\omega = 0.01 \text{ rad/s}$, and $x_v = (0 \ 0 \ 0)^T$. The process and measurements noise are zero-mean Gaussian with variance of 0.1 and 1, respectively. The nonlinear state dynamics and the measurement model are parametrized in the form (24). The $A(x)$ and $C(x)$ are given by

\[
A = \begin{bmatrix}
0_{2 \times 2} & 0_{2 \times 2} & 0_{2 \times 2} \\
\alpha^{T}_{\text{param}} & 0_{2 \times 2} & 0_{2 \times 2} \\
0_{(2n+1) \times 2} & 0_{2 \times 2} & 0_{2 \times 2}
\end{bmatrix},
\]

\[
C = \begin{bmatrix}
-N_1(\theta) & N_2(x_v) - N_2(\theta, l_1) & N_1(\theta) \\
-N_1(\theta) & N_2(x_v) - N_2(\theta, l_2) & 0_{2 \times 2} \\
-N_1(\theta) & N_2(x_v) - N_2(\theta, l_3) & 0_{2 \times 2} \\
-N_1(\theta) & N_2(x_v) - N_2(\theta, l_4) & 0_{2 \times 2} \\
-N_1(\theta) & N_2(x_v) - N_2(\theta, l_5) & 0_{2 \times 2}
\end{bmatrix}
\]  

(67)
where

\[ a_{\text{param}} = \frac{v(\cos(\theta) - 1)/\theta}{v\sin(\theta)/\theta}, \quad n = 3, \quad N_1(\cdot) \in \mathbb{R}^{2 \times 2} \quad \text{and} \quad N_2(\cdot) \in \mathbb{R}^{2 \times 1} \]

are nonlinear functions.

In the first simulation, the proposed observer using the LMI-SDARE algorithm (Section V-B1) is compared with the conventional SDDRE algorithm [21] and the EKF. We use \( \hat{x}(0) = (2, 2, 6, 2, 36, 2, 56, 4)^T \) to test the performance of the observers in the presence of large initial uncertainty. The pair \((A(x), C(\eta, x))\) in (67) satisfies Assumption 3 and Remark 4. Hence, the solutions of the Riccati equations for the EKF and SDDRE remain positive definite and bounded.

For the SDDRE algorithm, the filter parameters are selected as, \( R = I, \alpha = 0.15, \) and the initial error covariance \( P(0) = [x(0) - \hat{x}(0)][x(0) - \hat{x}(0)]^T. \) The matrix \( P(\hat{x}, t) \) is computed by integrating (34) using a single parametrization of \((A, C)\) and the observer gain is computed using (33). For the EKF noise covariance and process covariance are \( R_{\text{EKF}} = I \) and \( Q_{\text{EKF}} = 0.1I. \) For the LMI-SDARE algorithm, a convex combination of two different \( C \) matrix parametrizations is used with free parameters \( \eta_1 \) and \( \eta_2, \) represented by \( C(\eta, x) = \eta_1 C_1 + \eta_2 C_2. \)

Using the parametrization of \( C, \) the optimization problem in (66) is implemented using the cvx toolbox in Matlab [62], [56]. Filter parameters are selected as \( R = I, \alpha = 0.15, \kappa_1 = 0.1. \)

Since there is only one parametrization of \( A, Q_\eta, \) parameters are not be formed and constraints (58) and (59) are removed from the LMI implementation. The optimized parameters \( \eta_1 \) and \( \eta_2 \) are obtained for \( \alpha = 1.5. \) In Fig. 2, a comparison of the pose estimation errors and a comparison of the estimation error norm of the landmark state using all three filters are presented. From Fig. 2, it is observed that the EKF estimates fail to converge to the true value for a large initial uncertainty while the SDDRE and LMI-SDARE algorithms converge to the true value; i.e., the estimation error tends nearly to zero with the desired convergence property. The LMI-SDARE algorithm shows better performance than SDDRE and EKF, and provides a more systematic way to choose optimal parameters of the convex hull. In Fig. 3, the mean estimation error and \( \pm 95\% \) estimated confidence interval (\( \pm 2 \) standard deviation) for state 1 are plotted. The EKF overestimates its performance in terms of estimated standard deviation; i.e., the estimation errors may lie outside the estimated standard deviation. This causes statistical inconsistency in the EKF predictions and possible divergence as seen from the simulation. The predicted standard deviation of the LMI-SDARE is larger than that of the EKF, but the estimation error mean lies within the predicted standard deviation during the steady state; i.e., the filter is statistically consistent.

In the second simulation, the optimization problem (66) is solved for the LMI-SDARE algorithm by keeping the simulation parameters (i.e., the robot velocity, initial conditions of the estimator, and measurement covariance matrix) the same as the simulation case 1. The following sets of values for \( \Lambda = [A_1, A_2, A_3, A_4] \) are selected. \( A_b = [0, 0.5, 0.5, 0], A_b = [0, 1, 0, 0], A_c = [0.25, 0.25, 0.25, 0.25] \) for the objective function in (66). The multi-objective optimization in (66) is formulated using scalarization for finding Pareto optimal points [55]. In Fig. 4, a comparison of pose estimation errors is shown. From Fig. 4, it is observed that a larger \( A_4 \) corresponds to a faster convergence rate, \( A_4 \) tends to reduce the effects of noise, and a larger \( \kappa \) with a larger \( A_4 \) corresponds to robustness against noise in the estimation error steady-state response.

Fifty simulations are performed using the EKF, the conventional SDDRE, and the LMI-SDARE. The measurement and process noise, and initial state are selected as Gaussian random variables with zero-mean for noises and the mean initial state...
\[ \dot{x}(0) = (0.5, 0.5, 0.5, 0.5, 0.5, 0.5, 0.5, 0.5, 0.5, 0.5)\top. \]

The results of average root mean-squared errors (RMSE) and average worst case peak errors (PE) for state 1 and state 2 are tabulated in Table I. The LMI-SDARE outperforms the EKF and the conventional SDDRE filter in terms of RMSE and PE as seen from Table I.

**B. Lorentz Oscillator**

We consider the problem of state estimation for the Lorentz oscillator. The dynamics of the state \( x(t) = (x_1, x_2, x_3)^\top \) are described by

\[
\begin{align*}
\dot{x}_1 &= \sigma_L (x_2 - x_1), \\
\dot{x}_2 &= -\rho_L x_1 - x_2 - x_1 x_3, \\
\dot{x}_3 &= -\beta_L x_3 + x_1 x_2.
\end{align*}
\tag{68}
\]

The measurement equation is given by \( y = C x + \nu \), where \( C = [1, 0, 0] \). The parameters of the simulation are chosen as: \( \sigma_L = 10, \rho_L = 28, \beta_L = 8/3 \), \( x(0) = (0, 2, 0)^\top \), and \( \dot{x}(0) = (0, 1, 8, 0)^\top \). A zero-mean Gaussian white noise with variance of 0.1 is used as the measurement noise. Two different parametrizations \( A_1 \) and \( A_2 \) are selected and the optimization objective in (66) is used. A comparison of the state estimation errors computed using the LMI-SDARE algorithm and the deterministic observer presented in [14] is shown in Fig. 5. Although the observer in [14] is computationally simpler, the LMI-SDARE observer presented in this paper shows improved performance over the observer in [14] in terms of estimation error. Note that the algorithms in [10], [12] cannot be used for this model because the nonlinearity does not satisfy the required constraints.

**VII. CONCLUSION**

In this paper, a new exponentially converging observer based on a convex combination of multiple SDC parametrizations is presented for a class of Itô stochastic nonlinear systems perturbed by process and measurement noise. Stochastic incremental stability of the observer is studied with respect to a state-dependent metric \( M(x, t) \). It is shown that the mean-squared estimation error is exponentially bounded with the bound proportional to the measurement and process noise. The flexibility of non-uniqueness of the SDC form is utilized to obtain the improved convergence rate and disturbance-attenuation property by computing the observer gain via an LMI problem. The observer gain design problem is straightforward and can also handle state constraints related to preserving the observability of the SDC parametrization.

The performance comparison of the observer with the EKF and the conventional SDDRE filter is shown by robot navigation and Lorentz oscillator examples. Statistical inconsistency due to linearization is one of the reasons for filter divergence of the EKF. It is observed from the simulation examples that the LMI-SDARE filter is statistically consistent and yields smaller estimation errors. From a set of multiple numerical simulations, it is concluded that the LMI-SDARE filter outperforms the EKF and conventional SDDRE filters in terms of RMSE. For the LMI-SDARE algorithm, a solution to a SDLMI problem is required at each time instant to compute the gain, which can be efficiently computed using the interior-point methods.

**APPENDIX A**

**GRONWALL-TYPE LEMMA**

**Lemma 3:** Let \( g : [0, \infty) \to \mathbb{R} \) be a continuous function, and real numbers \( C > 0 \) and \( \lambda > 0 \). If

\[
\forall u, t, \quad 0 \leq u \leq t, \quad g(t) - g(u) \leq \int_{u}^{t} (-\lambda g(s) + C)ds \tag{69}
\]

then

\[
\forall t \geq 0, \quad g(t) \leq \frac{C}{\lambda} + \left[ g(0) - \frac{C}{\lambda} \right]^{+} e^{-\lambda t} \tag{70}
\]

where \( [\cdot]^{+} = \max(0, \cdot) \).
Proof: See [63].

APPENDIX B
COMPUTATION OF DIFFERENTIAL GENERATOR

The derivative of $V_2$ of the Lyapunov generator of $V(q(\mu,t), \delta q,t)$, defined in the proof of Theorem 2, can be computed as follows:

$$ V_2 = \int_0^1 \sum_{i=1}^n \sum_{j=1}^n P_{ij}^{-1} \left( \frac{\partial B_q(q,t)}{\partial \mu} \frac{\partial B_q(q,t)}{\partial \mu}^T \right) \, d\mu $$
$$ + \int_0^1 \sum_{i=1}^n \left( P_{ii}^{-1} \frac{\partial q}{\partial \mu} \right) \left( B_q(q,t) \frac{\partial B_q(q,t)}{\partial \mu} \right) \, d\mu $$
$$ + \frac{1}{2} \int_0^1 \left( \sum_{i=1}^n \sum_{j=1}^n \left( P_{ij}^{-1} (q(\mu,t), t) \right) \frac{\partial q}{\partial \mu} \frac{\partial q}{\partial \mu} \right) \left( B_q(q,t) \frac{\partial B_q(q,t)}{\partial \mu} \right) \, d\mu $$

(71)

where $q = q(\mu,t)$ such that $q(0,t) = x$ and $q(1,t) = \hat{x}$. The integrals of (71) are bounded above as follows:

$$ \int_0^1 \sum_{i=1}^n \sum_{j=1}^n P_{ij}^{-1} \left( \frac{\partial B_q(q,t)}{\partial \mu} \frac{\partial B_q(q,t)}{\partial \mu}^T \right) \, d\mu $$
$$ \leq \text{tr} \left( P^{-1}(x,t) B(x,t) B(x,t)^T \right) $$
$$ + \text{tr} \left( P^{-1}(\hat{x},t) (K(\hat{x},t) D(x,t)) (K(\hat{x},t) D(x,t))^T \right) $$

(72)

$$ \int_0^1 \sum_{i=1}^n \sum_{j=1}^n \left( P_{ii}^{-1} \frac{\partial q}{\partial \mu} \right) \left( B_q(q,t) \frac{\partial B_q(q,t)}{\partial \mu} \right) \, d\mu $$
$$ \leq -2\bar{p}_\varepsilon \left( \tilde{b}^2 + \frac{\tilde{b}^T \varepsilon_1}{\varepsilon_1} \text{tr} (P^2(x,t)) \right) \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu $$
$$ \leq -2\bar{p}_\varepsilon \left( \tilde{b}^2 + \frac{\tilde{b}^T \varepsilon_1}{\varepsilon_1} \text{tr} (P^2(x,t)) \right) \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu + \int_0^1 \frac{1}{\varepsilon_1} \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu $$

(73)

where $2a'b' \leq \varepsilon_1^{-1} a'^2 + \varepsilon_1 b'^2$, for an $\varepsilon_1 > 0$, for scalars $a'$ and $b'$ is used, \( \bar{p}_\varepsilon \) and \( \varepsilon_1 \) are defined in Assumption 6

$$ \frac{1}{2} \int_0^1 \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n \left( P_{ki}^{-1} (q(\mu,t)) \right) \frac{\partial q_k}{\partial \mu} \frac{\partial q_i}{\partial \mu} \left( \frac{\partial B_q(q,t)}{\partial \mu} \right) \, d\mu $$
$$ \leq \frac{1}{2} \bar{p}_\varepsilon \left( \tilde{b}^2 + \frac{\tilde{b}^T \varepsilon_1}{\varepsilon_1} \text{tr} (P^2(x,t)) \right) \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu $$

(74)

where \( \bar{p}_\varepsilon \) is defined in Assumption 6.

APPENDIX C
PROOF OF COROLLARY 1

Proof: The system (20) along with (31) can be written in the form (37)

$$ dq = f_v (q(\mu,t), t) dt + d_q (q(\mu,t), t) dt + B_q (q(\mu,t), t) dW $$

(75)

such that $q(0,t) = x$ and $q(1,t) = \hat{x}$, $B_q(0,t) = B(x,t)$ and $B_q(1,t) = K(\hat{x},t) D(x,t)$, and $d_q(0,t) = d(x,t)$ and $d_q(1,t) = 0$. Consider the Lyapunov function used in Theorem 2 $V(q, \delta q,t) = \int_0^1 (\delta q/\delta \mu)^T P^{-1}(q,\delta q,t) (\delta q/\delta \mu) \, d\mu$. Following the development in Theorem 2 and using (53), the differential generator (49) for the system (75) with respect to the Lyapunov function $V(q, \delta q,t)$ is given by

$$ L V \leq -2\alpha_3 \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T P^{-1}(q,t) \left( \frac{\partial q}{\partial \mu} \right) \, d\mu $$
$$ + \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T P^{-1}(\delta q/\delta \mu) \, d\mu $$
$$ + \int_0^1 \left( \frac{\partial d_q}{\partial \mu} \right)^T P^{-1}(\delta q/\delta \mu) \, d\mu + \bar{V}_2 $$

(76)

where $\bar{V}_2$ is defined in (50). Using the bound

$$ \int_0^1 \left( \frac{\partial q}{\partial \mu} \right)^T P^{-1}(\delta d_q/\delta \mu) + \left( \frac{\partial d_q}{\partial \mu} \right)^T P^{-1}(\delta q/\delta \mu) \, d\mu $$
$$ \leq \int_0^1 P^{-\frac{1}{2}} \left( \frac{\partial d_q}{\partial \mu} \right) \| P^{-\frac{1}{2}} \left( \frac{\partial q}{\partial \mu} \right) \| \, d\mu $$
$$ \leq \int_0^1 \frac{1}{\varepsilon_2} \| P^{-\frac{1}{2}} \left( \frac{\partial d_q}{\partial \mu} \right) \|^2 \, d\mu + \int_0^1 \varepsilon_2 \| P^{-\frac{1}{2}} \left( \frac{\partial q}{\partial \mu} \right) \|^2 \, d\mu $$

the following upper bound can be obtained:

$$ L V \leq -2\alpha_3 \frac{1}{\varepsilon_1} \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu $$
$$ + \frac{1}{\varepsilon_2} \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu + \bar{V}_2 $$
$$ \leq -(1-\theta)2\alpha_3 \int_0^1 \| \frac{\partial q}{\partial \mu} \|^2 \, d\mu $$
$$ + \frac{\tilde{p}}{\varepsilon_2} \| d(x,t) \|^2 + \bar{V}_2 $$

(77)

where $0 < \theta = (\varepsilon_2 \bar{p}/2 \alpha_3 \varepsilon_1) < 1$. By using Dynkin’s formula [3] and (77)

$$ E_{q_0} [ V(q(t), \delta q,t) - V(q(0), \delta q(0), 0) $$
$$ \leq E_{q_0} \left[ - (1-\theta)2\alpha_3 \| x(\tau) - \hat{x}(\tau) \|^2 $$
$$ + \frac{\tilde{p}}{\varepsilon_2} \| d(x, \tau) \|^2 + \delta_4 \right] \, d\tau $$

(78)
Using \( V(q(0), \delta q(0), 0) = \|x(0) - \hat{x}(0)\|_{p-1(0)}^2 \) and \( E_{q_0}[V(q(t), \delta q, t)] \geq 0 \) yield

\[
E_{q_0} \left[ \int_0^t \|x(t) - \hat{x}(t)\|^2 \, dt \right] \leq \frac{1}{(1 - \theta)\alpha_1^2} \left( \int_0^t \|x(t) - \hat{x}(0)\|^2 \, dt \right) \frac{\eta E_{q_0} \left[ \int_0^t \|x(t) - \hat{x}(0)\|^2 \, dt \right]}{\bar{E}(\delta q, t)}.
\]

(79)

Using the inequality \( E_{q_0} \left[ \int_0^t \|g(q(t) - \hat{g}(q(t))\|^2 \, dt \right] \leq \ell E_{q_0} \left[ \int_0^t \|x(t) - \hat{x}(0)\|^2 \, dt \right] \), where \( \ell \) is a constant, the following inequality can be obtained

\[
E_{q_0} \left[ \int_0^t \|g(q(t) - \hat{g}(q(t))\|^2 \, dt \right] \leq \frac{\ell}{\ell_1} \left( \|x(0) - \hat{x}(0)\|^2 \right) + E_{q_0} \left[ \int_0^t (\ell_2 \|d(x, \tau)\|^2 + \delta_1) \, d\tau \right].
\]
